## Diplomarbeit

Hypergraph Products

Referent: Professor Dr. Peter F. Stadler
Betreuer: Dipl.-Wirtsch.-Math. Marc Hellmuth

## Acknowledgments

Foremost, I want to thank Prof. Dr. Peter F. Stadler and Marc Hellmuth for supervising me and for their accompanying intellectual support. They always had essential hints whenever my thoughts were exhausted. Of course, I also want to thank my husband Philipp-Jens for his patience and for encouraging me so many times. Thanks to my family for their emotional and financial support throughout my whole studies. Last but not least, I want to thank my friends for all the nice time with coffee and cake, beer and discussions, playing games, watching films, parties and much more.

#### Abstract

In this work, new definitions of hypergraph products are presented. The main focus is on the generalization of the commutative standard graph products: the Cartesian, the direct and the strong graph product. We will generalize these well-known graph products to products of hypergraphs and show several properties like associativity, commutativity and distributivity w.r.t. the disjoint union of hypergraphs. Moreover, we show that all defined products of simple (hyper)graphs result in a simple (hyper)graph. We will see, for what kind of product the projections into the factors are (at least weak) homomorphisms and for which products there are similar connections between the hypergraph products as there are for graphs. Last, we give a new and more constructive proof for the uniqueness of prime factorization w.r.t. the Cartesian product than in [Studia Sci. Math. Hungar. 2: 285-290 (1967)] and moreover, a product relation according to such a decomposition. That might help to find efficient algorithms for the decomposition of hypergraphs w.r.t. the Cartesian product.

## Introduction

Within this diploma thesis we are concerned with hypergraph products as a generalization of graph products.
A (simple) graph $G$ is an object consisting of vertices and edges joining two vertices with each other, edges are thus two-element subsets of the vertex set. Graph theory occurs in various fields of science. For instance, social, computational, communication or transport networks can be described as graphs. They are furthermore an important tool in life science, physics, chemistry or optimization, to name just a few examples [5].

Many graphs can be constructed from smaller, more simple graphs by operations as unions, joins or multiplications with respect to a certain product, where many properties of the constructed graph can be immediately inferred from the constituents the graph is composed of. The operations we will focus on are the graph multiplications. Of course, there are various ways to define a product of two given graphs. If we restrict this amount of graph products to those which satisfy certain algebraic properties, we have in fact only four standard products: The Cartesian, direct, strong and lexicographic product. These are the only associative simple ${ }^{1}$ products that depend on the structure of both factors and for which at least one of the projections into a factor is a weak homomorphism, i.e. an edge is mapped either into an edge or a vertex, [26, 29].

The standard graph products have been widely investigated. The Cartesian product and besides, the strong product as well, have been introduced by G. Sabidussi (1960) in [37]. In this work the author also showed the uniqueness of prime factor decomposition of the Cartesian product. The direct product has been defined by A.N. Whitehead in 1912 as a product of binary relations [42]. In 1962, P. M. Weichsel introduced it on graphs as the Kronecker product [41]. The lexicographic product is due to F. Hausdorff (1914) [21], it was defined on graphs as the composition of graphs by Harary (1959) in [19]. It is the only non-commutative standard

[^0]product.

Hypergraph theory was introduced in the 1960s as a generalization of graph theory. Since then many applications for hypergraphs have been developed, for example in engineering, image processing, molecular biology or chemistry [6]. In a hypergraph more than two vertices may be linked, so the (hyper-)edges of a hypergraph are (arbitrary) subsets of the vertex set. A standard reference of this theory is due to C. Berge [3].
As for graphs, hypergraphs might be constructible from smaller hypergraphs, for example as products. One hypergraph product is given in [4], where the product of two hypergraphs is defined on the Cartesian product of their vertex sets, and the edges are the Cartesian (set) products of the edges of the factors. This product is the most common hypergraph product, see [7, 11, 35, 36]. A similar product was introduced by W. Imrich and P.F. Stadler as a product of neighborhood systems as a generalization of directed graphs in [31], where the authors also proved that these neighborhood systems have a unique prime factorization under some constraints. W. Dörfler and D. A. Waller introduced another hypergraph product 1980 [13], this is also treated by X. Zhu in 1992 [44]. However, these products are no graph products in the sense that a product of two (standard) graphs is a graph.

For consistency of hypergraph theory as a generalization of graph theory, one might consider the standard graph products and ask, how to extend them to hypergraph products, such that they fulfill certain algebraic properties that are also fulfilled in the case of graph products. Actually, there is no problem to extend the Cartesian product to hypergraphs. It has been introduced by W. Imrich in [23] as a product of set systems, i.e. hypergraphs. This hypergraph product is also considered for example in $[7,8,11]$. Besides, also the lexicographic product has been extended to hypergraphs by W. Imrich and G. Gaszt in [25] and is furthermore considered for example in [10, 38].

In this thesis, we will only focus on the commutative graph products and their generalization. Such hypergraph products are introduced in Chapter 2. We will be concerned with the Cartesian product of hypergraphs in Section 2.1. Basic properties of this product, some of them are stated in [23], are explicitly proved in that section. In the case of the direct product it becomes more difficult to define a suitable hypergraph product. The question is, how to transfer the adjacency properties of the factors to their product. In [13], the authors defined a product on $r$-uniform hypergraphs whose restriction to graphs coincides with the direct graph product. The problem is to extend this product to arbitrary hypergraphs. That is what we are concerned with in Section
2.2. We give three new definitions of hypergraph products. Two of them coincide with the hypergraph product defined in [13] in the class of $r$-uniform hypergraphs. The third one is modeled independently and was motivated by [31]. Furthermore, we prove basic properties of these products and we will see, for what reasons some of those products might fail for our purpose. Once found a proper definition for a direct product, there should be no problem to construct a strong product on hypergraphs by taking the union of the edge sets of the Cartesian and the direct product as the edge set of this product, as this is the case for graphs. This will be done in Section 2.3. Furthermore, basic properties of the strong product are shown.

In Chapter 3, we focus again on the Cartesian product. To be more precise, we study the prime factorization of a given hypergraph. In [23], it is shown, that the prime factor decomposition of a hypergraph is unique in the class of simple connected hypergraphs. Here we give an alternative, more constructive proof and provide a product relation according to the unique prime factor decomposition of a simple connected hypergraph.
But first we will start with some basic notions about hypergraphs and the commutative standard graph products in Chapter 1.

## 1 Basics

### 1.1 Hypergraphs

Within this section we provide a few basic concepts of hypergraph theory, which are needed in the main part of this thesis. Although we changed some notations, a standard reference for this theory is due to C. Berge [3].

A (finite) hypergraph $H=(V, \mathscr{E})$ consists of a finite set $V$ and a family $\mathscr{E}=\left\{E_{1}, \ldots, E_{m}\right\}$, such that:

$$
\begin{align*}
& E_{i} \neq \emptyset  \tag{1.1}\\
& E_{i} \subseteq V \tag{1.2}
\end{align*}
$$

for all $i \in\{1, \ldots, m\}$. A hypergraph $H=(V, \mathscr{E}), \mathscr{E}=\left\{E_{1}, \ldots, E_{m}\right\}$ is called simple if

$$
\begin{equation*}
E_{i} \subseteq E_{j} \quad \text { implies } \quad i=j, \tag{1.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|E_{i}\right| \geq 2 \quad \text { for all } i \in\{1, \ldots, m\} . \tag{1.4}
\end{equation*}
$$

In other words, there are no multiple edges, no edge of $H$ is contained in any other edge and each edge consists of at least two vertices.
The elements $v_{1}, \ldots, v_{n}$ of $V$ are called vertices and the sets $E_{1}, \ldots, E_{m}$ are the hyperedges, or simply edges of the hypergraph. For simplicity, we will refer to the family of edges $\mathscr{E}(H)$ of a hypergraph $H$ as edge set, although it need not to be a usual set.
If there is a risk of confusion we will denote the vertex set and the edge family of a hypergraph $H$ explicitly by $V(H)$ and $\mathscr{E}(H)$, respectively.

## 1 Basics

A hypergraph may be drawn as a set of points representing the vertices, an edge $E_{j}$ is represented by a simple closed curve enclosing its elements if $\left|E_{j}\right|>2$, for $\left|E_{j}\right|=2$ by a continuous curve joining its two elements, and by a loop if $\left|E_{j}\right|=1$.

Figure 1.1 shows two hypergraphs $H$ and $H^{\prime}$ with vertices $V(H)=V\left(H^{\prime}\right)=\left\{v_{1}, \ldots, v_{10}\right\}$ and edges $\mathscr{E}(H)=\left\{E_{1}, E_{2}, E_{3}, E_{4}, E_{5}, E_{6}, E_{7}\right\}$ and $\mathscr{E}\left(H^{\prime}\right)=\left\{E_{1}, E_{2}, E_{3}, E_{4}, E_{5}\right\}$, respectively. The hypergraph $H$ of the left hand side is not simple, since $E_{6} \subset E_{4}$ and $E_{7} \subset E_{3}$.

Figure 1.1: lhs: Hypergraph $H$. rhs: simple hypergraph $H^{\prime}$.

We say, two vertices $u$ and $v$ are adjacent in a hypergraph $H=(V, \mathscr{E})$ if there is an edge $E \in \mathscr{E}$ such that $u, v \in E$. If for two edges $E, F \in \mathscr{E}$ holds $E \cap F \neq \emptyset$, they are said to be incident. A vertex $v$ and an edge $E$ of $H$ are incident if $v \in E$.

The order of $H$, denoted by $n(H)$ is the number of vertices, the number of edges will be denoted by $m(H)$.

The rank of a hypergraph $H$ is $r(H)=\max _{j}\left|E_{j}\right|$, the anti-rank is $s(H)=\min _{j}\left|E_{j}\right|$. A uniform hypergraph $H$ is a hypergraph such that $r(H)=s(H)$. A simple uniform hypergraph of rank $r$ will be called r-uniform.

Walks, Paths, Distances A walk in a hypergraph $H=(V, \mathscr{E})$ is a sequence

$$
\begin{equation*}
\left(v_{0}, E_{1}, v_{1}, E_{2}, \ldots, E_{k}, v_{k}\right) \tag{1.5}
\end{equation*}
$$

where $E_{1}, \ldots, E_{k}$ are distinct edges, $v_{0}, \ldots, v_{k}$ are vertices, such that each $v_{i-1}, v_{i} \in E_{i}$. A $k$-cycle in a hypergraph is a closed walk consisting of $k$ edges. A path is a walk, where the vertices $v_{0}, \ldots, v_{k}$ are all distinct. Such a path is said to join the vertices $v_{0}$ and $v_{k}$, we will denote it by $P_{v_{0} v_{k}}$ and we will write $\left(E_{1}, E_{2}, \ldots, E_{k}\right)$ instead of (1.5) if possible. By a path between two edges

## 1 Basics

$E_{i}, E_{j}$ we then mean a path between two vertices $v_{i}, v_{j}$, such that $v_{i} \in E_{i}$ and $v_{j} \in E_{j}$.
The distance $d_{H}\left(v, v^{\prime}\right)$ of two vertices $v_{0}, v_{k}$ of $H$ is the length of the shortest path joining them, i.e. the number of edges contained in the path,

$$
d_{H}\left(v, v^{\prime}\right)=\min \left\{|E(P)|: P \text { joins } v \text { and } v^{\prime}\right\} .
$$

If there is no path joining them, we set $d_{H}\left(v, v^{\prime}\right)=\infty$.
A hypergraph $H=(V, \mathscr{E})$ is called connected, if any two vertices are joined by a path, that means for each two vertices $v, v^{\prime}$ of $H$ we have $d_{H}\left(v, v^{\prime}\right)<\infty$.

Partial Hypergraphs For a hypergraph $H=(V, \mathscr{E})$ we call $H^{\prime}=(W, \mathscr{F})$ a partial hypergraph of $H$ if $W \subseteq V$ and $\mathscr{F} \subseteq \mathscr{E}$. We then write $H^{\prime} \subseteq H$. A partial hypergraph $H^{\prime}=(W, \mathscr{F}) \subseteq H=$ $(V, \mathscr{E})$ is generated by the edge set $\mathscr{F}$ if $W=\bigcup_{E \in \mathscr{F}} E$. It is induced by the vertex set $W$ if $\mathscr{F}=(E \in \mathscr{E} \mid E \subseteq W)$. Such an induced partial hypergraph will be denoted by $H^{\prime}=\langle W\rangle$. Note, that a partial hypergraph of a simple hypergraph is always simple.

Figure 1.2 shows three partial hypergraphs $H_{1}, H_{2}$ and $H_{3}$ of the Hypergraph $H$ in Figure 1.1, with the vertex sets $V\left(H_{1}\right)=V\left(H_{2}\right)=\left\{v_{1}, v_{2}, v_{3}, v_{4}, v_{6}, v_{7}, v_{8}\right\} \subset V(H)$ and $V\left(H_{3}\right)=$ $\left\{v_{1}, v_{2}, v_{3}, v_{4}, v_{6}, v_{7}\right\} \subset V(H)$, respectively and with edge sets $\mathscr{E}\left(H_{1}\right)=\mathscr{E}\left(H_{3}\right)=\left\{E_{1}, E_{3}\right\} \subset$ $\mathscr{E}(H)$ and $\mathscr{E}\left(H_{2}\right)=\left\{E_{1}, E_{3}, E_{6}, E_{7}\right\} \subset \mathscr{E}(H)$, respectively.

Figure 1.2: Partial hypergraphs $H_{1}, H_{2}$ and $H_{3}$ of the non simple hypergraph $H$ of Figure 1.1
$H_{1}$ is neither an induced partial hypergraph, since $E_{6}, E_{7} \subset V\left(H_{1}\right)$ but $E_{6}, E_{7} \notin \mathscr{E}\left(H_{1}\right)$ although they are contained in $\mathscr{E}(H)$, nor is it a generated hypergraph, since $v_{8} \notin E_{1} \cup E_{3}$. While $H_{2}$ is an induced and a generated partial hypergraph, $H_{3}$ is generated but not induced, since $E_{7} \notin \mathscr{E}\left(H_{3}\right)$, although $E_{7} \subset V\left(H_{3}\right)$.

By a path between two partial hypergraphs $H^{\prime}, H^{\prime \prime}$ of a hypergraph $H$ is meant a path in $H$ between two vertices $v$ and $w$ such that $v \in V\left(H^{\prime}\right)$ and $w \in V\left(H^{\prime \prime}\right)$, respectively. The distance

## 1 Basics

$d_{H}\left(H^{\prime}, H^{\prime \prime}\right)$ between two partial hypergraphs $H^{\prime}, H^{\prime \prime}$ is the length of the shortest path between two vertices of the respective partial hypergraphs.

A partial hypergraph $H^{\prime} \subseteq H$ is called convex, if all shortest paths in $H$ between two vertices in $H^{\prime}$ are also contained in $H^{\prime}$.

Homomorphisms For two hypergraphs $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ a homomorphism from $H_{1}$ into $H_{2}$ is a mapping $\varphi: V_{1} \rightarrow V_{2}$ such that $\varphi(E)=\left\{\varphi\left(v_{1}\right), \ldots, \varphi\left(v_{r}\right)\right\}$ is an edge in $H_{2}$, whenever $E=\left\{v_{1}, \ldots, v_{r}\right\}$ is an edge in $H_{1}$. A mapping $\varphi: V_{1} \rightarrow V_{2}$ is a weak homomorphism if edges are mapped either on edges or on vertices.

A bijective homomorphism $\varphi$ is called an isomorphism if $\varphi(E) \in \mathscr{E}_{2}$ if and only if $E \in \mathscr{E}_{1}$. We say, $H_{1}$ and $H_{2}$ are isomorphic, in symbols $H_{1} \cong H_{2}$ if there exists an isomorphism between them. In this case the two hypergraphs have the same structure.

If $\varphi$ is the identity, $H_{1}$ and $H_{2}$ are said to be the same, $H_{1}=H_{2}$, i.e., $V\left(H_{1}\right)=V\left(H_{2}\right)$ and $\mathscr{E}\left(H_{1}\right)=\mathscr{E}\left(H_{2}\right)$.

### 1.2 Graph Products

An (undirected) graph is a pair $G=(V, E)$ of vertex set $V$ and a family $E$ consisting of unordered pairs of elements of $V$, the edges of $G$. If an edge $e$ of $G$ consists of the same vertices of $G, e=\{u, u\}$, this will be called a loop. Such an edge will be denoted by $\{u\}$ instead of $\{u, u\}$. A graph can be seen as a special hypergraph, whose edges are restricted to contain at most 2 elements. That is, a graph $G$ is a hypergraph with $\operatorname{rank} r(G)=2$. Therefore, all definitions of the latter section may be transfered to graphs as well. A simple graph is then a 2 -uniform hypergraph. The class of simple graphs will be denoted by $\Gamma$, that of simple graphs with loops by $\Gamma_{0}$. In the following, by a subgraph is meant a partial hypergraph of a graph. More information about graphs and graph theory can be found for example in [9] and [20].

In this section we give a short overview about the commutative standard graph products, that are the Cartesian product, the direct product and the strong product. We will restrict our considerations to their definition and a few basic algebraic properties. All assertions stated here, including their proofs and in addition, more detailed information about product graphs can be found in [29].

## 1 Basics

### 1.2.1 The Cartesian Product

The Cartesian product $G=G_{1} \square G_{2}$ of two graphs $G_{1}=\left(V_{1}, E_{1}\right)$ and $G_{2}=\left(V_{2}, E_{2}\right)$ is defined on the vertex set $V(G)=V_{1} \times V_{2}$ with edge set

$$
E(G)=\left\{\left\{\left(u_{1}, u_{2}\right),\left(v_{1}, v_{2}\right)\right\} \mid\left\{u_{1}, v_{1}\right\} \in E_{1}, u_{2}=v_{2}, \text { or } u_{1}=v_{1},\left\{u_{2}, v_{2}\right\} \in E_{2}\right\} .
$$

The Cartesian product satisfies several algebraic properties such like associativity, commutativity and distributivity with respect to the disjoint union, it is connected if and only if both factors are. The one vertex graph $K_{1}$ is a unit with respect to the Cartesian product, i.e. $G \square K_{1} \cong K_{1} \square G \cong G$ for any graph $G$. The Cartesian product $G=\square_{i=1}^{n} G_{i}$ of arbitrary many factors $G_{i}$ is well defined [28].

Figure 1.3: Cartesian Product of a graph $G$ and a path $P_{3}$ on 3 vertices

The mapping $p_{i}: V\left(\square_{i=1}^{n} G_{i}\right) \rightarrow V\left(G_{i}\right)$ defined by $p_{i}(v)=v_{i}$ for $v=\left(v_{1}, v_{2}, \ldots, v_{n}\right)$ is called projection on the $i$-th factor of $G$, and $v_{i}$ is then the $i$-th coordinate of $v$. Each of the $p_{i}$ is a weak homomorphism for all $i=i, \ldots, n$, since edges are mapped on edges or vertices. The restriction of $p_{i}$ to the induced subgraph of $G$ whose vertices differ from a vertex $w$ only in the $i$-th coordinate is then an isomorphism, since

$$
\left\langle\left\{v \in V(G) \mid p_{j}(v)=w_{j}, \text { for all } j \neq i\right\}\right\rangle
$$

is isomorphic to $G_{i}$. This induced subgraph is called $G_{i}$-layer through $w$, denoted by $G_{i}^{w}$. Notice, that $G_{i}^{w}$ are convex subgraphs of $G$, while $G_{i}$ is no subgraph of $G$. For $u \in V\left(G_{i}^{w}\right)$ we have $G_{i}^{u}=G_{i}^{w}$. If $u \notin V\left(G_{i}^{w}\right)$, then $G_{i}^{u} \neq G_{i}^{w}$, moreover $V\left(G_{i}^{u}\right) \cap V\left(G_{i}^{w}\right)=\emptyset$.

We are now in the position to give an equivalent definition of the Cartesian product in terms of projections as follows (see [37]).
For $G=\square_{i=1}^{n} G_{i}, G_{i}=\left(V_{i}, E_{i}\right)$ and $I=\{1, \ldots, n\}$ we have

## 1 Basics

(1) $V(G)=V_{1} \times V_{2} \times \ldots \times V_{n}$
(2) $\{u, v\} \in E(G), u, v \in V(G)$ iff there is an index $j \in I$, s.t. $\left\{p_{j}(u), p_{j}(v)\right\} \in E_{j}$ and $p_{i}(u)=$ $p_{i}(v)$ for all $i \neq j, i \in I$.

A graph $G$ is called prime with respect to a given product if it cannot be represented as a product of nontrivial factors. For the Cartesian product this means $G$ is prime if $G=G_{1} \square G_{2}$ implies $G_{1}=K_{1}$ or $G_{2}=K_{1}$. A set $\left\{G_{1}, \ldots, G_{n}\right\}$ of graphs is called a prime factorization of $G$ if $G=\square_{i=1}^{n} G_{i}$, where $G_{i}$ is prime and $G_{i} \neq K_{1}$ for $1 \leq i \leq n([1])$.

Proposition 1.1. [29] Every graph $G$ has a prime factor decomposition with respect to the Cartesian product. The number of prime factors is at most $\log _{2}|V(G)|$.

Cartesian Product graphs and their prime factor decomposition have been widely investigated, also from an algorithmic point of view, see $[1,14,15,30,37,40,43]$.

Theorem 1.1. [29] Prime factorization is not unique for the Cartesian product in the class of non-connected simple graphs.

The next result was first proved by G. Sabidussi in 1960. V.G. Vizing gave an alternative proof in 1963.

Theorem 1.2. [37, 40] Every connected graph $G$ has a unique prime factor decomposition with respect to the Cartesian product.

### 1.2.2 The Direct Product

As the Cartesian product, the direct product of two graphs $G=G_{1} \times G_{2}$ is defined on the Cartesian product of their vertex sets $V(G)=V\left(G_{1}\right) \times V\left(G_{2}\right)$. A pair of vertices $\left\{\left(u_{1}, u_{2}\right),\left(v_{1}, v_{2}\right)\right\}$ is an edge in $G$ if and only if $\left\{u_{1}, v_{1}\right\}$ is an edge in $G_{1}$ and $\left\{u_{2}, v_{2}\right\}$ is an edge in $G_{2}$. More formal:

$$
E\left(G_{1} \times G_{2}\right)=\left\{\left\{\left(u_{1}, u_{2}\right),\left(v_{1}, v_{2}\right)\right\} \mid\left\{u_{1}, v_{1}\right\} \in E\left(G_{1}\right),\left\{u_{2}, v_{2}\right\} \in E\left(G_{2}\right)\right\} .
$$

While the factors of a connected direct product must be connected, the converse does not hold in general. As an example see Figure 1.4.

Figure 1.4: Direct product of two paths $P_{3} \times P_{5}$. Although the factors are connected, their product consists of two connected components

As the Cartesian product the direct product satisfies several algebraic properties such like associativity, commutativity and distributivity. But it has no unit in the class of simple graphs. If we admit graphs with loops, then the one-vertex graph with a loop is a unit for the direct product [29].
The projections of a direct product into its factors are not just weak homomorphisms as for the Cartesian product, they are homomorphisms.
In terms of projections the direct product can be defined as follows:
For $G=\times_{i=1}^{n} G_{i}, G_{i}=\left(V_{i}, E_{i}\right)$ and $I=\{1, \ldots, n\}$ we have
(1) $V(G)=V_{1} \times V_{2} \times \ldots \times V_{n}$
(2) $\{u, v\} \in E(G), u, v \in V(G)$ iff $\left\{p_{i}(u), p_{i}(v)\right\} \in E_{i}$ for all $i \in I$.

In distinction from the Cartesian product the prime factorization is not only non-unique in the class of non-connected graphs:

Theorem 1.3. [29] Prime factorization with respect to the direct product is neither unique in the class of non-connected graphs with loops nor in the class of connected simple graphs.

The next result was proved by R. McKenzie in 1971. In this work the direct product is called "cardinal product".

Theorem 1.4. [34] Let $G$ be a finite, non bipartite ${ }^{1}$ connected graph in $\Gamma_{0}$. Then $G$ has unique prime factor decomposition with respect to the direct product in $\Gamma_{0}$.

[^1]
## 1 Basics

### 1.2.3 The Strong Product

The strong product $G=G_{1} \boxtimes G_{2}$ of two graphs $G_{1}$ and $G_{2}$ is defined on the Cartesian product of the vertex sets of the factors, $V(G)=V\left(G_{1}\right) \times V\left(G_{2}\right)$. two distinct vertices $\left(u_{1}, u_{2}\right)$ and $\left(v_{1}, v_{2}\right)$ are adjacent if

$$
\begin{gathered}
\left\{u_{1}, v_{1}\right\} \in E\left(G_{1}\right) \text { and }\left\{u_{2}, v_{2}\right\} \in E\left(G_{2}\right), \text { or } \\
\left\{u_{1}, v_{1}\right\} \in E\left(G_{1}\right) \text { and } u_{2}=v_{2}, \text { or } \\
u_{1}=v_{1} \text { and }\left\{u_{2}, v_{2}\right\} \in E\left(G_{2}\right)
\end{gathered}
$$

We observe that

$$
\begin{equation*}
E\left(G_{1} \boxtimes G_{2}\right)=E\left(G_{1} \square G_{2}\right) \cup E\left(G_{1} \times G_{2}\right) \tag{1.6}
\end{equation*}
$$

The strong product is associative, commutative, distributive w.r.t the disjoint union and has $K_{1}$ as unit. Hence the strong product $G=\boxtimes_{i=1}^{n} G_{i}$ of arbitrary many factors $G_{i}$ is well defined. It is connected if and only if all of its factors are. The projections of a strong product graph into its factors are weak homomorphisms [29].

Figure 1.5: Strong product of two paths $P_{3} \times P_{5}$. The thick edges are Cartesian edges, the thin ones are non-Cartesian edges

We can define the strong product, analogously to [37], in terms of the projection as follows: For $G=\boxtimes_{i=1}^{n} G_{i}, G_{i}=\left(V_{i}, E_{i}\right)$ and $I=\{1, \ldots, n\}$ we have
(1) $V(G)=V_{1} \times V_{2} \times \ldots \times V_{n}$
(2) $\{u, v\} \in E(G), u, v \in V(G)$ iff there is an index set $J \subseteq I$, s.t. $\left\{p_{j}(u), p_{j}(v)\right\} \in E_{j}$ for all $j \in J$ and $p_{i}(u)=p_{i}(v)$ for all $i \in I \backslash J$.

As for the Cartesian product, each $G_{i}^{w}$-layer

$$
\left\langle\left\{v \in V(G) \mid p_{j}(v)=w_{j}, \text { for all } j \neq i\right\}\right\rangle
$$

## 1 Basics

is isomorphic to $G_{i}$. But they are not convex in general, contrary to the Cartesian product.
The edges of a strong product $G=\boxtimes_{i=1}^{n} G_{i}$ that differ in exactly one coordinate are called Cartesian the others non-Cartesian, see Figure 1.5. In Equation (1.6) the Cartesian edges correspond to the first term $E\left(G_{1} \square G_{2}\right)$ on the right hand side and those which are non-Cartesian to the second term $E\left(G_{1} \times G_{2}\right)$.

The strong product can be considered as a special case of the direct one:
For a graph $G \in \Gamma$ let $\mathcal{L} G$ denote the graph in $\Gamma_{0}$, which is formed from $G$ by adding a loop to each vertex of $G$. On the other hand, for a graph $G^{\prime} \in \Gamma_{0}$ let $\mathcal{N} G^{\prime}$ denote the graph in $\Gamma$ which emerges from $G^{\prime}$ by deleting all loops. Then we have for $G_{1}, G_{2} \in \Gamma$ :

$$
\begin{equation*}
G_{1} \boxtimes G_{2}=\mathcal{N}\left(\mathcal{L} G_{1} \times \mathcal{L} G_{2}\right) \tag{1.7}
\end{equation*}
$$

As for the Cartesian product, every graph has a prime factor decomposition with respect to the strong product. In the class of non-connected graphs, this need not be unique. The following result was proved by W. Dörfler and W. Imrich in 1970.

Theorem 1.5. [12] Every connected graph G has unique prime factor decomposition with respect to the strong product.

## 2 Hypergraph Products

A first definition of a "direct" product $H_{1} \times H_{2}$ of two hypergraphs $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=$ $\left(V_{2}, \mathscr{E}_{2}\right)$ on the vertex set $V\left(H_{1} \times H_{2}\right)=V_{1} \times V_{2}$ with edge set $\mathscr{E}\left(H_{1} \times H_{2}\right)=\left\{E_{1} \times E_{2} \mid E_{1} \in\right.$ $\left.\mathscr{E}_{1}, E_{2} \in \mathscr{E}_{2}\right\}$ can be found in [4]. Another definition of a hypergraph product is given by W. Dörfler and D. A. Waller in [13] and is also considered by X. Zhu in [44]:

For two hypergraphs $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ the product $H_{1} \times H_{2}$ is the hypergraph with vertex set $V\left(H_{1} \times H_{2}\right)=V_{1} \times V_{2}$ and a subset $E=\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{k}, y_{k}\right)\right\}$ of $V\left(H_{1} \times H_{2}\right)$ is an edge of $H_{1} \times H_{2}$ if and only if $\left\{x_{1}, \ldots, x_{k}\right\} \in \mathscr{E}_{1}$ and $\left\{y_{1}, \ldots, y_{k}\right\} \in \mathscr{E}_{2}$, where $x_{1}, \ldots, x_{k}$ and $y_{1}, \ldots, y_{k}$ need not to be distinct.
However, these products do not specialize to graphs. That is, the product of two graphs seen as 2-uniform hypergraphs is not a usual graph, but a 4-uniform hypergraph.

In this chapter we want to introduce hypergraph products, which coincide with the commutative standard graph products, defined in the previous section. In particular, we are interested in hypergraph products $\star$ that satisfy the following requirements:

1. $V\left(H_{1} \star H_{2}\right)=V\left(H_{1}\right) \times V\left(H_{2}\right)$
2. The restriction of the product $\star$ on graphs coincides with the corresponding graph product.
3. Associativity.
4. Commutativity.
5. Distributivity with respect to the disjoint union.
6. If $H_{1}$ and $H_{2}$ are simple then $H_{1} \star H_{2}$ is simple.
7. The projections $p_{i}: V\left(H_{1} \star H_{2}\right) \rightarrow V\left(H_{i}\right)$ for $i \in\{1,2\}$ are at least weak homomorphisms. In the first section we are concerned with the Cartesian product of hypergraphs. It was introduced by W. Imrich in 1967 as the Cartesian product of set systems as a generalization of the Cartesian graph product [23].

In the second section we will introduce three direct products, and we will see, for what reasons some of them might fail for our purpose.

In the third section we will be concerned with the strong hypergraph product. As we have seen in Section 1.2.3 the edge set of the strong product of two graphs is the union of the edge sets of their Cartesian and direct product. There is no reason to change this for hypergraphs.

### 2.1 The Cartesian Product

Let $H_{1}$ and $H_{2}$ be two Hypergraphs. The Cartesian product $H=H_{1} \square H_{2}$ has vertex set $V(H)=$ $V\left(H_{1}\right) \times V\left(H_{2}\right)$, that is the Cartesian product of the vertex sets of the factors and the edge set

$$
\begin{aligned}
\mathscr{E}(H)= & \left\{\{x\} \times F: x \in V\left(H_{1}\right), F \in \mathscr{E}\left(H_{2}\right)\right\} \\
& \cup\left\{E \times\{y\}: E \in \mathscr{E}\left(H_{1}\right), y \in V\left(H_{2}\right)\right\} .
\end{aligned}
$$

Thus, the set $\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}, x_{i} \in V\left(H_{1}\right), y_{i} \in V\left(H_{2}\right), i=1, \ldots, r$, is an edge in $\mathscr{E}\left(H_{1} \square H_{2}\right)$ if and only if either
(i) $\left\{x_{1}, \ldots, x_{r}\right\}$ is an edge in $\mathscr{E}\left(H_{1}\right)$ and $y_{1}=\ldots=y_{r}$, or
(ii) $\left\{y_{1}, \ldots, y_{r}\right\}$ is an edge in $\mathscr{E}\left(H_{2}\right)$ and $x_{1}=\ldots=x_{r}$.

The Cartesian product of hypergraphs was introduced by W. Imrich [23]. We consider it for sake of completeness and prove explicitly some basic properties.

Figure 2.1 shows an example of a Cartesian product of two hypergraphs $H$ and $E_{3}$, where $E_{3}$ is is the hypergraph which consists of a single edge with three vertices.

H

$E_{3}$

Figure 2.1: Hypergraphs $H$ and $E_{3}$ and their Cartesian product $H \square E_{3}$

Let an edge $E$ in $\mathscr{E}(H)$ be denoted by
(i) $E_{i y}$ if $E=E_{i} \times\{y\}$, where $E_{i} \in \mathscr{E}\left(H_{1}\right)$ and $y \in V\left(H_{2}\right)$
(ii) $E_{x j}$ if $E=\{x\} \times E_{j}$, where $x \in V\left(H_{1}\right)$ and $E_{j} \in \mathscr{E}\left(H_{2}\right)$

We define the projection of a Cartesian product $H=H_{1} \square H_{2}$ into one of the factors $H_{i}, i \in$ $\{1,2\}$ by the mapping $p_{i}: V(H) \rightarrow V\left(H_{i}\right)$, with $p_{i}(v)=v_{i}$, where $v=\left(v_{1}, v_{2}\right) \in V(H)$. By $p_{i}(X)$ we denote the set $\left\{p_{i}(x): x \in X\right\}$ for an $X \subseteq V(H)$. The projections of a Cartesian product of hypergraphs into its factors are weak homomorphisms, as edges are either mapped onto edges or onto vertices:

$$
\begin{array}{rll}
p_{1}\left(E_{x j}\right)=x \in V\left(H_{1}\right) & \text { and } & p_{2}\left(E_{i y}\right)=E_{i} \in \mathscr{E}\left(H_{1}\right) \\
p_{1}\left(E_{x j}\right)=E_{j} \in \mathscr{E}\left(H_{2}\right) & \text { and } & p_{2}\left(E_{i y}\right)=y \in V\left(H_{2}\right)
\end{array}
$$

Lemma 2.1. The Cartesian Product is associative.
Proof. To proof associativity we need to show that the mapping $V\left(\left(H_{1} \square H_{2}\right) \square H_{3}\right) \rightarrow$ $V\left(H_{1} \square\left(V_{2} \square V_{3}\right)\right)$ defined by $((x, y), z) \mapsto(x,(y, z))$ with $x \in V\left(H_{1}\right), y \in V\left(H_{2}\right)$ and $z \in V\left(H_{3}\right)$ is an isomorphism. Clearly, it is bijective.
Let $\left\{\left(\left(x_{1}, y_{1}\right), z_{1}\right), \ldots,\left(\left(x_{r}, y_{r}\right), z_{r}\right)\right\}$ be an edge in $\left(H_{1} \square H_{2}\right) \square H_{3}$. Then the following cases can occur:
(i) $\left(x_{1}, y_{1}\right)=\ldots=\left(x_{r}, y_{r}\right) \in V\left(H_{1} \square H_{2}\right)$, i.e. $x_{1}=\ldots=x_{r} \in V\left(H_{1}\right)$ and $y_{1}=\ldots=y_{r} \in V\left(H_{2}\right)$, and therefore $\left\{z_{1}, \ldots, z_{r}\right\} \in \mathscr{E}\left(H_{3}\right)$, or

## 2 Hypergraph Products

(ii) $z_{1}=\ldots=z_{r} \in V\left(H_{3}\right)$ and therefore $\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\} \in \mathscr{E}\left(H_{1} \square H_{2}\right)$. Then
(a) $x_{1}=\ldots=x_{r} \in V\left(H_{1}\right)$ and $\left\{y_{1}, \ldots, y_{r}\right\} \in \mathscr{E}\left(H_{2}\right)$, or
(b) $y_{1}=\ldots=y_{r} \in V\left(H_{2}\right)$ and $\left\{x_{1}, \ldots, x_{r}\right\} \in \mathscr{E}\left(H_{1}\right)$.

Altogether we have either
(1) $\left\{x_{1}, \ldots, x_{r}\right\}$ is an edge in $H_{1}$ and the $y_{i}$ and $z_{i}$ resp. are equal, or
(2) $\left\{y_{1}, \ldots, y_{r}\right\}$ is an edge in $H_{2}$ and the $x_{i}$ and $z_{i}$ resp. are equal, or
(3) $\left\{z_{1}, \ldots, z_{r}\right\}$ is an edge in $H_{3}$ and the $x_{i}$ and $y_{i}$ resp. are equal.

But this is equivalent to the following:
(i) $x_{1}=\ldots=x_{r} \in V\left(H_{1}\right)$ and $\left\{\left(y_{1}, z_{1}\right), \ldots,\left(y_{r}, z_{r}\right)\right\} \in \mathscr{E}\left(H_{2} \square H_{3}\right)$ because of (2) and (3), respectively, or
(ii) $\left\{x_{1}, \ldots, x_{r}\right\} \in \mathscr{E}\left(H_{1}\right)$ and $\left(y_{1}, z_{1}\right)=\ldots=\left(y_{r}, z_{r}\right) \in V\left(H_{2} \square H_{3}\right)$ because of (1).

Therefore, $\left\{\left(x_{1},\left(y_{1}, z_{2}\right)\right), \ldots,\left(x_{r},\left(y_{r}, z_{r}\right)\right)\right\}$ is an edge in $H_{1} \square\left(H_{2} \square H_{3}\right)$. That means the image of a subset $F \subseteq V\left(\left(H_{1} \square H_{2}\right) \square H_{3}\right)$ is an edge in $H_{1} \square\left(H_{2} \square H_{3}\right)$ if and only if it is an edge in $\left(H_{1} \square H_{2}\right) \square H_{3}$.
Hence, the mapping defined above is an isomorphism, which completes the proof.

Due to the symmetry of the definition we can state
Lemma 2.2. The Cartesian product is commutative.
Notice, that commutativity and associativity is meant in the sense of identifying isomorphic hypergraphs.
The one vertex hypergraph $K_{1}$ is a unit with respect to the Cartesian product, i.e., $K_{1} \square H \cong$ $H \square K_{1} \cong H$ for any hypergraph $H$. The isomorphism is given by the projection into the factor $H$. For two vertex-disjoint hypergraphs $H_{1}$ and $H_{2}$ their disjoint union, denoted as $H_{1}+H_{2}$ is defined by $V\left(H_{1}+H_{2}\right)=V\left(H_{1}\right) \cup V\left(H_{2}\right)$ and $\mathscr{E}\left(H_{1}+H_{2}\right)=\mathscr{E}\left(H_{1}\right) \cup \mathscr{E}\left(H_{2}\right)$.

Lemma 2.3. The Cartesian product is left and right distributive together with the disjoint union as addition.

## 2 Hypergraph Products

Proof. Let $H_{1}, H_{2}$ and $H_{3}$ be hypergraphs and furthermore, let $H_{2}$ and $H_{3}$ be vertex-disjoint. Then we have for the vertex set of $H_{1} \square\left(H_{2}+H_{3}\right)$ :

$$
\begin{align*}
V\left(H_{1} \square\left(H_{2}+H_{3}\right)\right) & =V\left(H_{1}\right) \times\left(V\left(H_{2}\right) \cup V\left(H_{3}\right)\right) \\
& =\left(V\left(H_{1}\right) \times V\left(H_{2}\right)\right) \cup\left(V\left(H_{1}\right) \times V\left(H_{3}\right)\right) \\
& =V\left(H_{1} \square H_{2}+H_{1} \square H_{3}\right) \tag{2.1}
\end{align*}
$$

and for the edge set:

$$
\begin{align*}
\mathscr{E}\left(H_{1} \square\left(H_{2}+H_{2}\right)\right)= & \left\{\{x\} \times F: x \in V\left(H_{1}\right), F \in \mathscr{E}\left(H_{2}+H_{3}\right)\right\} \\
& \cup\left\{E \times\{y\}: E \in \mathscr{E}\left(H_{1}\right), y \in V\left(H_{2}+H_{3}\right)\right\} \\
= & \left\{\{x\} \times F: x \in V\left(H_{1}\right), F \in \mathscr{E}\left(H_{2}\right) \cup \mathscr{E}\left(H_{3}\right)\right\} \\
& \cup\left\{E \times\{y\}: E \in \mathscr{E}\left(H_{1}\right), y \in V\left(H_{2}\right) \cup V\left(H_{3}\right\}\right. \\
= & \left\{\{x\} \times F: x \in V\left(H_{1}\right), F \in \mathscr{E}\left(H_{2}\right)\right\} \\
& \cup\left\{\{x\} \times F: x \in V\left(H_{1}\right), F \in \mathscr{E}\left(H_{3}\right)\right\} \\
& \cup\left\{E \times\{y\}: E \in \mathscr{E}\left(H_{1}\right), y \in V\left(H_{2}\right)\right\} \\
& \cup\left\{E \times\{y\}: E \in \mathscr{E}\left(H_{1}\right), y \in V\left(H_{3}\right)\right\} \\
= & \left\{\{x\} \times F: x \in V\left(H_{1}\right), F \in \mathscr{E}\left(H_{2}\right)\right\} \\
& \cup\left\{E \times\{y\}: E \in \mathscr{E}\left(H_{1}\right), y \in V\left(H_{2}\right)\right\} \\
& \cup\left\{\{x\} \times F: x \in V\left(H_{1}\right), F \in \mathscr{E}\left(H_{3}\right)\right\} \\
& \cup\left\{E \times\{y\}: E \in \mathscr{E}\left(H_{1}\right), y \in V\left(H_{3}\right)\right\} \\
= & \mathscr{E}\left(H_{1} \square H_{2}\right) \cup \mathscr{E}\left(H_{1} \square H_{3}\right) \\
= & \mathscr{E}\left(H_{1} \square H_{2}+H_{1} \square H_{3}\right) \tag{2.2}
\end{align*}
$$

## Hence

$$
H_{1} \square\left(H_{2}+H_{3}\right)=H_{1} \square H_{2}+H_{1} \square H_{3},
$$

From analogous considerations we can infer

$$
\left(H_{1}+H_{2}\right) \square H_{3}=H_{1} \square H_{3}+H_{2} \square H_{3},
$$

for vertex-disjoint $H_{1}$ and $H_{2}$.

## 2 Hypergraph Products

Lemma 2.4. The Cartesian product $H=\square_{i=1}^{n} H_{i}$ of hypergraphs $H_{i}$ is connected if and only if all of its factors $H_{i}$ are connected.

Proof. Because of associativity and commutativity of the Cartesian product it suffices to show the assertion for $n=2$, therefore let $H=H_{1} \square H_{2}$.
First assume $H_{1}$ and $H_{2}$ to be connected. Let $v=(x, y)$ and $v^{\prime}=\left(x^{\prime}, y^{\prime}\right)$ be two arbitrary vertices in $V(H)$. Consider a path $P_{x x^{\prime}}=\left(E_{1}, \ldots, E_{r}\right)$ from $x$ to $x^{\prime}$ in $H_{1}$ and a path $P_{y y^{\prime}}=\left(F_{1}, \ldots, F_{s}\right)$ from $y$ to $y^{\prime}$ in $H_{2}$. Then $\left(E_{1 y}, \ldots, E_{r y}\right)$ is a path from $(x, y)$ to $\left(x^{\prime}, y\right)$ in $H$ and $\left(F_{x^{\prime} 1}, \ldots, F_{x^{\prime} s}\right)$ is a path from $\left(x^{\prime}, y\right)$ to $\left(x^{\prime}, y^{\prime}\right)$ in $H$. Hence $\left(E_{1 y}, \ldots, E_{r y}, F_{x^{\prime} 1}, \ldots, F_{x^{\prime} s}\right)$ is a path from $v$ to $v^{\prime}$ in $H$.
W.l.o.g. suppose now $H_{1}$ is not connected. It is then the disjoint union of two hypergraphs, $H_{1}=H_{1}^{\prime}+H_{1}^{\prime \prime}$. Since the Cartesian product is distributive with respect to the disjoint union, we have $H=H_{1}^{\prime} \square H_{2}+H_{1}^{\prime \prime} \square H_{2}$, that is $H$ is the disjoint union of two hypergraphs, i.e., $H$ is not connected.

Lemma 2.5. The Cartesian product $H=\square_{i=1}^{n} H_{i}$ of hypergraphs $H_{i}$ is simple if and only if all of its factors $H_{i}$ are simple.

Proof. Because of associativity and commutativity of the Cartesian product, it suffices to show the assertion for $n=2$, therefore let $H=H_{1} \square H_{2}$.

First let $H_{1}$ and $H_{2}$ be simple and suppose $H$ is not simple. We have to examine several cases:
Suppose $H$ contains at least one loop $\{(x, y)\}=\{x\} \times\{y\}$. Then, it follows, $\{x\}$ is an edge in $H_{1}$, i.e., a loop, or $\{y\}$ is a loop in $H_{2}$. Both contradicts the fact, that $H_{1}$ and $H_{2}$ are simple. Thus, $|E| \geq 2$ for all $E \in \mathscr{E}(H)$.
Now, let $E_{x j} \subseteq E_{x^{\prime} j^{\prime}}$. It follows immediately that $x=x^{\prime}$ and $E_{j} \subseteq E_{j^{\prime}}$. Since $H_{2}$ is simple, we have $j=j^{\prime}$, and therefore it follows $(x j)=\left(x^{\prime} j^{\prime}\right)$. By commutativity, the same holds for the case $E_{i y} \subseteq E_{i^{\prime} y^{\prime}}$.
Now assume $E_{x j} \subseteq E_{i y}$, i.e. $\left(\{x\} \times E_{j}\right) \subseteq\left(E_{i} \times\{y\}\right)$. Then we have $E_{j} \subseteq\{y\}$ thus $E_{j}=\{y\}$, contradicting that $H_{2}$ is simple. The same argumentation holds for $E_{i y} \subseteq E_{x j}$.
That means, $H_{1} \square H_{2}$ is simple.
Now assume (at least) one of the factors is not simple, w.l.o.g. say $H_{1}$. Then there are two edges $E_{i}, E_{j} \in \mathscr{E}\left(H_{1}\right)$, such that $E_{i} \subseteq E_{j}, i \neq j$ or there is an $E_{i} \in \mathscr{E}\left(H_{1}\right)$ with $\left|E_{i}\right|=1$, say $E_{i}=\{x\}$. In the first case we have for any $y \in V\left(H_{2}\right), E_{i y}=E_{i} \times\{y\} \subseteq E_{j} \times\{y\}=E_{j y}$ and $(i y) \neq(j y)$, hence $H_{1} \square H_{2}$ is not simple. In the second case, we have $\left|E_{i y}\right|=|\{(x, y)\}|=1$ for any $y \in V\left(H_{2}\right)$ and $H_{1} \square H_{2}$ would not be simple.

## 2 Hypergraph Products

The Cartesian Product of arbitrarily many factors $H=\square_{i=1}^{n} H_{i}$ is now well defined. Thus, we can extend the concept of the projections. For $H=\square_{i=1}^{n} H_{i}$ and $j \in\{1, \ldots, n\}$ we define $p_{j}$ : $V\left(\square_{i=1}^{n} H_{i}\right) \rightarrow V\left(H_{j}\right)$ through $p_{j}(v)=v_{j}$, for $v=\left(v_{1}, \ldots, v_{n}\right)$, the projection into the $j$-th factor $H_{j}$ of $H$. We then call $v_{j}$ the $j$-th coordinate of $v$. Clearly, the projections $p_{j}, j \in\{1, \ldots, n\}$, $n \geq 2$ are weak homomorphisms as well.

According to [37] the Cartesian product of hypergraphs can be described in terms of projections as follows:
For $H=\square_{i=1}^{n} H_{i}$, with $H_{i}=\left(V_{i}, \mathscr{E}_{i}\right)$ and $I=\{1, \ldots, n\}$ we have
(1) $V(H)=V_{1} \times V_{2} \times \ldots \times V_{n}$,
(2) for $E \subseteq V(H)$ we have $E \in \mathscr{E}(H)$ if and only if there is an $i \in I$, s.t.
(i) $p_{i}(E) \in \mathscr{E}_{i}$ and
(ii) $\left|p_{j}(E)\right|=1$ for all $j \in I \backslash\{i\}$.

Notice, that $\left|p_{i}(E)\right|=|E|$ holds.
Let $w \in V(H)$ be a vertex of $H$. The partial hypergraph of $H$ induced by all vertices of $H$ which differ from $w$ exactly in the $j$-th coordinate is isomorphic to $H_{j}$, more formal

$$
\left\langle\left\{v \in V(H) \mid p_{k}(v)=w_{k} \text { for } k \neq j\right\}\right\rangle \cong H_{j}
$$

We will call this partial hypergraph the $H_{j}$-layer through $w$, denoted as $H_{j}^{w}$. The isomorphism $H_{j}^{w} \rightarrow H_{j}$ is then the projection $p_{j}$. For $u \in V\left(H_{j}^{w}\right)$ we have $H_{j}^{u}=H_{j}^{w}$ and moreover $V\left(H_{j}^{u}\right) \cap$ $V\left(H_{j}^{w}\right)=\emptyset$ if and only if $u \notin V\left(H_{j}^{w}\right)$.

Figure 2.2: Cartesian product $H \square E_{3}$ (cf. Figure 2.1), red $H^{w}$-layer

Figure 2.2 shows the Cartesian product of a hypergraph $H$ and the hypergraph $E_{3}$ consisting of a single edge with three vertices, see Figure 2.1 and a layer of the hypergraph $H$ through the vertex $w, H^{w}$, highlighted by red edges.

## Summary

To conclude this section, we summarize the preceding results. For the Cartesian product holds:

1. The restriction of this product on graphs is the Cartesian graph product.
2. Associativity.
3. Commutativity.
4. Distributivity with respect to the disjoint union.
5. The product of two simple hypergraphs is simple.
6. The projections of a product hypergraph onto its factors are weak homomorphisms.

As an open problem, it remains to examine if this product has a unique prime factorization. This will be done in Chapter 3.

### 2.2 The Direct Product

To find suitable direct hypergraph products, we have to claim that they are closed under the restriction on 2-uniform hypergraphs. The most simple way to ensure this is to define a product which preserves the rank of one of its factors, and therefore is closed on $r$-uniform hypergraphs in general. Besides, it is also possible to define a direct hypergraph product, which does not need to be $r$-uniform although its factors are.
In this section we will introduce three different direct products. The direct product $\check{x}$, which preserves the minimal rank of two factors, the direct product $\hat{x}$, which preserves the maximal rank of two factors and the direct product $\tilde{x}$, which does not preserve any rank of its factors.

### 2.2.1 r-Uniformity Preserving Direct Product

Recall, that for two given graphs, $G_{1}$ and $G_{2}, e=\left\{\left(x_{1}, x_{2}\right),\left(y_{1}, y_{2}\right)\right\}$ is an edge in $G_{1} \times G_{2}$, for $x_{i}, y_{i} \in V\left(G_{i}\right), i=1,2$, if and only if $\left\{x_{1}, y_{1}\right\}$ is an edge in $G_{1}$ and $\left\{x_{2}, y_{2}\right\}$ is an edge in $G_{2}$.

## 2 Hypergraph Products

There is no problem to extend this definition to $r$-uniform hypergraphs:
Let $H_{1}$ and $H_{2}$ be two $r$-uniform hypergraphs. We define their direct product $H_{1} \times H_{2}$ by

$$
\begin{equation*}
\mathscr{E}\left(H_{1} \times H_{2}\right):=\left\{\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\} \mid\left\{x_{1}, \ldots, x_{r}\right\} \in \mathscr{E}\left(H_{1}\right),\left\{y_{1}, \ldots, y_{r}\right\} \in \mathscr{E}\left(H_{2}\right)\right\} . \tag{2.3}
\end{equation*}
$$

Thus $E=\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}, x_{i} \in V\left(H_{1}\right), y_{i} \in V\left(H_{2}\right), i=1, \ldots, r$, is an edge in $H_{1} \times H_{2}$ if and only if
(i) $\left\{x_{1}, \ldots, x_{r}\right\}$ is an edge in $H_{1}$ and
(ii) $\left\{y_{1}, \ldots, y_{r}\right\}$ is an edge in $H_{2}$.

Figure 2.3 shows a direct product of two hypergraphs that consists only of a single edge with three vertices.

Figure 2.3: Direct product $E_{3} \times E_{3}$

Clearly, for $r=2$ this is the direct graph product.
This product was introduced by W. Dörfler and D. A. Waller in [13]. However, it is only defined on $r$-uniform hypergraphs. A natural question is how to extend this to a product between two arbitrary, non-uniform hypergraphs.

## Minimal Rank Preserving Direct Product

Now we introduce a direct hypergraph product which preserves the the minimal rank of one of its factors.
Let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ be two hypergraphs. Then their direct product $\check{x}$ is defined on the Cartesian product of the vertex set, and a subset $E=\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$ of $V_{1} \times V_{2}$ is an edge in $H_{1} \times H_{2}$ if and only if

## 2 Hypergraph Products

(i) $\left\{x_{1}, \ldots, x_{r}\right\}$ is an edge in $H_{1}$ and $\left\{y_{1}, \ldots, y_{r}\right\}$ is the subset of an edge in $H_{2}$, or
(ii) $\left\{x_{1}, \ldots, x_{r}\right\}$ is the subset of an edge in $H_{1}$ and $\left\{y_{1}, \ldots, y_{r}\right\}$ is an edge in $H_{2}$

More formal, for two hypergraphs $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right), H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$, we define their direct product $\check{\times}$ by the edge set

$$
\begin{aligned}
\mathscr{E}\left(H_{1} \check{\times} H_{2}\right): & =\left\{\bigcup_{x \in E}\{(x, \pi(x))\} \mid \pi: E \rightarrow F \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2}\right\} \\
& \cup\left\{\bigcup_{y \in F}\left\{\left(\pi^{\prime}(y), y\right)\right\} \mid \pi^{\prime}: F \rightarrow E \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2}\right\} .
\end{aligned}
$$

Let an edge $\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$ in $H=H_{1} \check{\times} H_{2}$ be denoted by
(i) $E_{i \pi}$ if $\left\{x_{1}, \ldots, x_{r}\right\}=E_{i} \in \mathscr{E}_{1}$ and $\left\{y_{1}, \ldots, y_{r}\right\} \subseteq F_{j} \in \mathscr{E}_{2}$, where $\pi: E_{i} \rightarrow F_{j}$ is the injective mapping defined by $\pi\left(x_{k}\right)=y_{k}$, for all $k \in\{1, \ldots, r\}$, and
(ii) $E_{\pi^{\prime} j}$ if $\left\{y_{1}, \ldots, y_{r}\right\}=F_{j} \in \mathscr{E}_{2}$ and $\left\{x_{1}, \ldots, x_{r}\right\} \subseteq E_{i} \in \mathscr{E}_{1}$, where $\pi^{\prime}: F_{j} \rightarrow E_{i}$ is the injective mapping defined by $\pi^{\prime}\left(y_{k}\right)=x_{k}$ for all $k \in\{1, \ldots, r\}$.

Notice, if there exists no edge of the form $E_{i \pi}$, all edges of $H$ are of the form $E_{\pi^{\prime} j}$ and vice versa.

Figure 2.4 shows a direct product $\check{x}$ of a hypergraph $H$ and the hypergraph $E_{3}$, which consists only of a single edge with three vertices.

Figure 2.4: Direct product $\check{\times}, H \check{\times} E_{3}$

The restriction of the direct product $\check{x}$ to $r$-uniform hypergraphs is the product defined in Equation (2.3), hence the restriction of this product to simple graphs coincides with the direct

## 2 Hypergraph Products

graph product.
We have:

$$
r\left(H_{1} \check{\times} H_{2}\right)=\min \left\{r\left(H_{1}\right), r\left(H_{2}\right)\right\}
$$

and

$$
s\left(H_{1} \check{\times} H_{2}\right)=\min \left\{s\left(H_{1}\right), s\left(H_{2}\right)\right\}
$$

where $r(H)$ and $s(H)$ denote the rank and the anti-rank, respectively of a hypergraph $H$.
Lemma 2.6. The direct product $\check{\times}$ is associative.
Proof. Let $H_{1}=\left(V_{1} \mathscr{E}_{1}\right), H_{2}=\left(V_{2}, \mathscr{E}_{2}\right), H_{3}=\left(V_{3}, \mathscr{E}_{3}\right)$ be given hypergraphs. As for the Cartesian product we proof associativity by showing that the mapping $\psi: V\left(H_{1} \check{\times}\left(H_{2} \check{\times} H_{3}\right)\right) \rightarrow$ $V\left(\left(H_{1} \check{\times} H_{2}\right) \check{\times} H_{3}\right)$ defined by $(x,(y, z)) \mapsto((x, y), z)$, with $x \in V_{1}, y \in V_{2}$ and $z \in V_{3}$, is an isomorphism. Obviously $\psi$ is bijective, hence, it remains to show the homomorphism property, i.e., we have to show that $E$ is an edge in $H_{1} \check{\times}\left(H_{2} \check{\times} H_{3}\right)$ if and only if $\psi E$ is an edge in $\left(H_{1} \check{\times} H_{2}\right) \check{\times} H_{3}$. Let $E=\left\{\left(\left(x_{1}, y_{1}\right), z_{1}\right), \ldots,\left(\left(x_{r}, y_{r}\right), z_{r}\right)\right\}$ be an edge in $\left(H_{1} \check{\times} H_{2}\right) \check{\times} H_{3}$.
There are two cases which can occur. First, $\left\{z_{1}, \ldots, z_{r}\right\}$ is an edge in $H_{3}$ and $\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$ is thus a subset of an edge in $H_{1} \check{\times} H_{2}$, hence $\left\{x_{1}, \ldots, x_{r}\right\}$ and $\left\{y_{1} \ldots, y_{r}\right\}$ must be subsets of edges in $H_{1}$ and $H_{2}$ respectively. But then $\left\{\left(y_{1}, z_{1}\right), \ldots,\left(y_{r}, z_{r}\right)\right\}$ is an edge in $H_{2} \check{\times} H_{3}$, thus $\psi E=\left\{\left(x_{1},\left(y_{1}, z_{1}\right)\right), \ldots,\left(x_{r},\left(y_{r}, z_{r}\right)\right)\right\}$ is an edge in $H_{1} \check{\times}\left(H_{2} \check{\times} H_{3}\right)$.
Second, $\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$ is an edge in $H_{1} \check{\times} H_{2}$ and $\left\{z_{1}, \ldots, z_{r}\right\}$ is a subset of an edge in $H_{3}$. Then, $\left\{x_{1}, \ldots, x_{r}\right\}$ is an edge in $H_{1}$ and $\left\{y_{1} \ldots, y_{r}\right\}$ is a subset of an edge in $H_{2}$, or vice versa. In the first case $\left\{\left(y_{1}, z_{1}\right), \ldots,\left(y_{r}, z_{r}\right)\right\}$ is a subset of an edge in $H_{2} \check{\times} H_{3}$, hence, $\psi E$ is an edge in $H_{1} \check{\times}\left(H_{2} \check{\times} H_{3}\right)$, and in the second case $\left\{\left(y_{1}, z_{1}\right), \ldots,\left(y_{r}, z_{r}\right)\right\}$ is an edge in $H_{2} \check{\times} H_{3}$ and thus $\psi E$ is an edge in $H_{1} \check{\times}\left(H_{2} \check{\times} H_{3}\right)$.

This implies that, whenever $E$ is an edge in $\left(H_{1} \check{\times} H_{2}\right) \check{\times} H_{3}$, then $\psi E$ is an edge in $H_{1} \check{\times}\left(H_{2} \check{\times} H_{3}\right)$. The converse, i.e., if $\psi E$ is an edge in $H_{1} \check{\times}\left(H_{2} \check{\times} H_{3}\right)$ then $E$ is an edge in $\left(H_{1} \check{\times} H_{2}\right) \check{\times} H_{3}$, is shown analogously. Hence, it holds $\left(H_{1} \check{\times} H_{2}\right) \check{\times} H_{3} \cong H_{1} \check{\times}\left(H_{2} \check{\times} H_{3}\right)$.

As for the Cartesian product, we have due to the symmetry of its definition:
Lemma 2.7. The direct product $\check{x}$ is commutative
Distributivity with respect to the disjoint union as addition follows by set-theoretic considerations similar to those as in the case of the Cartesian product.

## 2 Hypergraph Products

Lemma 2.8. The direct product $\check{\times}$ is left and right distributive with respect to the disjoint union as addition.

Proof. Let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right), H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ and $H_{3}=\left(V_{3}, \mathscr{E}_{3}\right)$ be hypergraphs and let $H_{2}$ and $H_{3}$ be vertex-disjoint. Then we have

$$
\begin{aligned}
\mathscr{E}\left(H_{1} \check{\times}\left(H_{2}+H_{3}\right)\right)= & \left\{\bigcup_{x \in E}\{(x, \pi(x))\} \mid \pi: E \rightarrow F \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2} \cup \mathscr{E}_{3}\right\} \\
& \cup\left\{\bigcup_{y \in F}\left\{\left(\pi^{\prime}(y), y\right)\right\} \mid \pi^{\prime}: F \rightarrow E \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2} \cup \mathscr{E}_{3}\right\} \\
= & \left\{\bigcup_{x \in E}\{(x, \pi(x))\} \mid \pi: E \rightarrow F \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2}\right\} \\
& \cup\left\{\bigcup_{x \in E}\{(x, \pi(x))\} \mid \pi: E \rightarrow F \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{3}\right\} \\
& \cup\left\{\bigcup_{y \in F}\left\{\left(\pi^{\prime}(y), y\right)\right\} \mid \pi^{\prime}: F \rightarrow E \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2}\right\} \\
& \cup\left\{\bigcup_{y \in F}\left\{\left(\pi^{\prime}(y), y\right)\right\} \mid \pi^{\prime}: F \rightarrow E \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{3}\right\} \\
= & \left\{\bigcup_{x \in E}\{(x, \pi(x))\} \mid \pi: E \rightarrow F \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2}\right\} \\
& \cup\left\{\bigcup_{y \in F}\left\{\left(\pi^{\prime}(y), y\right)\right\} \mid \pi^{\prime}: F \rightarrow E \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2}\right\} \\
& \cup\left\{\bigcup_{x \in E}\{(x, \pi(x))\} \mid \pi: E \rightarrow F \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{3}\right\} \\
& \cup\left\{\bigcup_{y \in F}\left\{\left(\pi^{\prime}(y), y\right)\right\} \mid \pi^{\prime}: F \rightarrow E \text { injective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{3}\right\} \\
= & \mathscr{E}\left(H_{1} \check{x} H_{2}\right) \cup \mathscr{E}\left(H_{1} \check{\times} H_{3}\right) \\
= & \mathscr{E}\left(\left(H_{1} \check{x} H_{2}\right)+\left(H_{1} \check{\times} H_{3}\right)\right)
\end{aligned}
$$

With the same arguments as in Equation (2.1) we can conclude $V\left(H_{1} \check{\times}\left(H_{2}+H_{3}\right)\right)=$ $V\left(\left(H_{1} \check{\times} H_{2}\right)+\left(H_{1} \check{\times} H_{3}\right)\right)$ and hence, it follows $H_{1} \check{\times}\left(H_{2}+H_{3}\right)=\left(H_{1} \check{\times} H_{2}\right)+\left(H_{1} \check{\times} H_{3}\right)$.
Analogously we can conclude $\left(H_{1}+H_{2}\right) \check{\times} H_{3}=\left(H_{1}+H_{3}\right) \check{\times}\left(H_{2}+H_{3}\right)$ for vertex disjoint hypergraphs $H_{1}$ and $H_{2}$.

Note, that the direct product $\check{x}$ of two connected hypergraphs need not to be connected.
Lemma 2.9. The direct product $\check{\times}, H=\check{x}_{i=1}^{n} H_{i}$, of simple hypergraphs $H_{i}$ is simple.
Proof. Because of associativity and commutativity of the direct product $\check{x}$, it suffices to prove the assertion for $n=2$. Therefore, let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ be two simple hypergraphs

## 2 Hypergraph Products

and suppose $H=H_{1} \check{\times} H_{2}$ is not simple. Then several cases can occur.
Suppose first $H$ contains at least one loop $\{(x, y)\}$. Then, it follows, $\{x\}$ is an edge in $H_{1}$, i.e., a loop, or $\{y\}$ is a loop in $H_{2}$, contradicting the fact, that $H_{1}$ and $H_{2}$ are simple. Thus, $|E| \geq 2$ for all $E \in \mathscr{E}(H)$.
Now, assume there is an edge $E_{i_{1} \pi_{1}}$ contained in an edge $E_{i_{2} \pi_{2}}$. If there are no edges of the form $E_{i \pi}$ in $H$, we consider the hypergraph $H_{2} \check{\times} H_{1}$.

We have $E_{i_{s} \pi_{s}}=\bigcup_{x \in E_{i_{s}}}\left\{\left(x, \pi_{s}(x)\right)\right\}$, where $\pi_{s}: E_{i_{s}} \rightarrow F_{j_{s}}$ is an injective mapping, with $E_{i_{s}} \in \mathscr{E}_{1}$ and $F_{j_{s}} \in \mathscr{E}_{2}$, for $s=1,2$. It follows

$$
E_{i_{1}}=\bigcup_{x \in E_{i_{1}}}\{x\} \subseteq \bigcup_{x \in E_{i_{2}}}\{x\}=E_{i_{2}}
$$

and since $H_{1}$ is simple we conclude $i_{1}=i_{2}$. Furthermore we have

$$
\pi_{1}\left(E_{i_{1}}\right)=\bigcup_{x \in E_{i_{1}}}\left\{\pi_{1}(x)\right\} \subseteq \bigcup_{x \in E_{i_{2}}}\left\{\pi_{2}(x)\right\} \subseteq F_{j_{2}}
$$

hence $\pi_{1}$ is a mapping from $E_{i_{1}}$ into $F_{j_{2}}$ and since $\pi_{1}(x)=\pi_{2}(x)$ must hold for all $x \in E_{i_{1}}=E_{i_{2}}$ we have $\pi_{1}=\pi_{2}$. Thus, $E_{i_{1} \pi_{1}} \subseteq E_{i_{2} \pi_{2}}$ implies $\left(i_{1} \pi_{1}\right)=\left(i_{2} \pi_{2}\right)$. Analogously we can conclude that $E_{\pi_{1}^{\prime} j_{1}} \subseteq E_{\pi_{2}^{\prime} j_{2}}$ implies $\left(\pi_{1}^{\prime} j_{1}\right)=\left(\pi_{2}^{\prime} j_{2}\right)$.
Now assume we have $E_{i \pi} \subseteq E_{\pi^{\prime} j}$ with $E_{i \pi}=\bigcup_{x \in E_{i}}\{(x, \pi(x))\}$, where $\pi: E_{i} \rightarrow F_{j^{\prime}}$, and $E_{\pi^{\prime} j}=$ $\bigcup_{y \in F_{j}}\left\{\left(\pi^{\prime}(y), y\right)\right\}, \pi^{\prime}: F_{j} \rightarrow E_{i^{\prime}}$, respectively. Remark that $\pi\left(E_{i}\right) \subseteq F_{j^{\prime}}$ as well as $\pi^{\prime}\left(F_{j}\right) \subseteq E_{j^{\prime}}$. It follows

$$
E_{i}=\bigcup_{x \in E_{i}}\{x\} \subseteq \bigcup_{y \in F_{j}}\left\{\pi^{\prime}(y)\right\}=\pi^{\prime}\left(F_{j}\right) \subseteq E_{i^{\prime}}
$$

and since $H_{1}$ is simple, we conclude $i=i^{\prime}$. But then it follows $E_{i}=\pi^{\prime}\left(F_{j}\right)$, i.e. $\pi^{\prime}$ : $F_{j} \rightarrow E_{i}$ is surjective and therefore bijective. Thus we can write $E_{\pi^{\prime} j}=\bigcup_{y \in F_{j}}\left\{\left(\pi^{\prime}(y), y\right)\right\}=$ $\bigcup_{x \in E_{i}}\left\{\left(x, \pi^{\prime-1}(x)\right)\right\}=E_{i \pi^{\prime-1}}$. Since $\pi(x)=y$ if and only if $\pi^{\prime}(y)=x$ for all $x \in E_{i}$ we obtain $\pi^{\prime-1}=\pi$. Hence $E_{i \pi} \subseteq E_{\pi^{\prime} j}$ with $E_{i \pi}=\bigcup_{x \in E_{i}}\{(x, \pi(x))\}$ implies $(i \pi)=\left(\pi^{\prime} j\right)$.
The fact that $E_{\pi^{\prime} j} \subseteq E_{i \pi}$ implies $(i \pi)=\left(\pi^{\prime} j\right)$ as well is shown analogously. Thus, $H$ is simple.

The direct product $\check{x}$ does not have a unit in the class of simple hypergraphs, since the direct product has no unit for simple graphs. Also in the class of non simple hypergraphs, there exists no unit. To be more precise, neither the one vertex hypergraph $K_{1}$ without edges, nor the one with a loop, $\mathcal{L} K_{1}$, is a unit for the direct product $\check{x}$ :

Example 2.1. Consider the (hyper)graphs $K_{2}=(\{a, b\},\{\{a, b\}\})$, consisting of two vertices and one single edge containing these vertices and $\mathcal{L} K_{1}=(\{x\},\{\{x\}\})$, respectively. Then:

$$
V\left(K_{2} \check{\times} \mathcal{L} K_{1}\right)=\{(a, x),(b, x)\}=V\left(K_{2} \times \mathcal{L} K_{1}\right)
$$

but

$$
\mathscr{E}\left(K_{2} \check{\times} \mathcal{L} K_{1}\right)=\{\{(a, x)\},\{(b, x)\}\} \neq\{\{(a, x),(b, x)\}\}=\mathscr{E}\left(K_{2} \times \mathcal{L} K_{1}\right),
$$

where $\check{\times}$ denotes the direct product $\check{\times}$ of hypergraphs, and $\times$ denotes the (usual) direct graph product. Therefore $K_{2} \check{\times} \mathcal{L} K_{1} \neq K_{2} \times \mathcal{L} K_{1}$.

The latter example implies, that the direct product $\check{x}$ does not coincide with the direct graph product in the class of graphs with loops. Furthermore, it turns out, that the direct product $\check{x}$ has no unique prime factorization in general, as shown in the following example:

Example 2.2. Let $E_{3}$ be the hypergraph consisting of three vertices and one edge containing these vertices. Then we have

$$
K_{2} \check{\times} E_{3} \cong K_{2} \check{\times} E_{3} .
$$

Figure 2.5: Two different pairs of hypergraphs whose direct product $\check{x}$ is isomorphic

Furthermore, consider the projections of such a product hypergraph into its factors:

## 2 Hypergraph Products

Example 2.3. The direct product $\check{\times}$ as in Figure 2.5, $H=E_{3} \check{\times} K_{2}$, has edge set
$\mathscr{E}(H)=\{\{(1, a),(2, b)\},\{(1, a),(3, b)\},\{(2, a),(1, b)\},\{(2, a),(3, b)\},\{(3, a),(1, b)\},\{(3, a),(2, b)\}\}$.
The Factor $E_{3}$ has edge set $\mathscr{E}\left(E_{3}\right)=\{\{1,2,3\}\}$. For the projection $p_{E_{3}}$ into this factor holds:

$$
\begin{aligned}
& p_{E_{3}}(\{(1, a),(2, b)\})=p_{E_{3}}(\{(2, a),(1, b)\})=\{1,2\} \notin \mathscr{E}\left(E_{3}\right) \\
& p_{E_{3}}(\{(1, a),(3, b)\})=p_{E_{3}}(\{(3, a),(1, b)\})=\{1,3\} \notin \mathscr{E}\left(E_{3}\right) \\
& p_{E_{3}}(\{(2, a),(3, b)\})=p_{E_{3}}(\{(3, a),(2, b)\})=\{2,3\} \notin \mathscr{E}\left(E_{3}\right) .
\end{aligned}
$$

In general, we have

$$
p_{1}\left(E_{i \pi}\right)=E_{i} \in \mathscr{E}_{1} \quad \text { and } \quad p_{2}\left(E_{\pi^{\prime} j}\right)=F_{j} \in \mathscr{E}_{2}
$$

but

$$
p_{1}\left(E_{\pi^{\prime} j}\right)=\pi^{\prime}\left(F_{j}\right)
$$

and this need neither be a vertex nor an edge in $H_{1}$, as well as

$$
p_{2}\left(E_{i \pi}\right)=\pi\left(E_{i}\right)
$$

and this need neither be a vertex nor an edge in $H_{2}$, too.
So the projections indeed preserve adjacency, i.e., two vertices in a direct product $\check{x}$ hypergraph are adjacent, whenever they are adjacent in both of the factors. However, the projections need not to be (weak) homomorphisms in general.

Thus, we not consider this product further.

## Maximal Rank Preserving Direct Product

In the last paragraph we defined a product where the size of two multiplied edges is reduced to the size of the smaller one. This might be the reason for the non-uniqueness of the prime factor decomposition as seen in Example 2.2, and that the projections of a product into its factors need not to be weak homomorphisms.
Now we will define a direct product, such that an edge, we get by multiplying two edges, preserves the size of the bigger edge of the factors.
For this product most of the basic properties are shown analogously as for the direct product $\check{x}$.

Let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ be two hypergraphs. Then their direct product $\hat{\mathrm{x}}$ is defined on the Cartesian product of the vertex set, and a subset $E=\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$ of $V_{1} \times V_{2}$ is an edge in $H_{1} \hat{\times} H_{2}$ if and only if
(i) $\left\{x_{1}, \ldots, x_{r}\right\}$ is an edge in $H_{1}$ and there is an edge $F \in \mathscr{E}_{2}$ of $H_{2}$ such that $\left\{y_{1}, \ldots y_{r}\right\}$ is a family of elements of $F$, and $F \subseteq\left\{y_{1}, \ldots, y_{r}\right\}$, or
(ii) $\left\{y_{1}, \ldots, y_{r}\right\}$ is an edge in $H_{2}$ and there is an edge $E \in \mathscr{E}_{1}$ of $H_{1}$ such that $\left\{x_{1}, \ldots x_{r}\right\}$ is a family of elements of $E$, and $E \subseteq\left\{x_{1}, \ldots, x_{r}\right\}$.

More formal, we define the direct product $\hat{\chi}$ of two hypergraphs $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=$ $\left(V_{2}, \mathscr{E}_{2}\right)$ by the edge set

$$
\begin{aligned}
\mathscr{E}^{( }\left(H_{1} \hat{\times} H_{2}\right): & =\left\{\bigcup_{x \in E}\{(x, \varphi(x))\} \mid \varphi: E \rightarrow F \text { surjective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2}\right\} \\
& \cup\left\{\bigcup_{y \in F}\left\{\left(\varphi^{\prime}(y), y\right)\right\}: \varphi^{\prime}: F \rightarrow E \text { surjective, } E \in \mathscr{E}_{1}, F \in \mathscr{E}_{2}\right\} .
\end{aligned}
$$

Figure 2.6 shows the direct product $\hat{x}$ of the hypergraph $E_{3}$, which consists of one single edge of size 3 and the $K_{2}$, consisting of one single edge with two vertices. Another example can be seen in Figure 2.3 at the beginning of this section.

Figure 2.6: Direct product $\hat{x}, E_{3} \hat{\otimes} K_{2}$

Let an edge $\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$ in $H=H_{1} \hat{\times} H_{2}$ be denoted by
(i) $E_{i \varphi}$ if $\left\{x_{1}, \ldots, x_{r}\right\}=E_{i} \in \mathscr{E}_{1}$ and $\mathscr{E}_{2} \ni F_{j} \subseteq\left\{y_{1}, \ldots, y_{r}\right\} \subseteq F_{j}^{r}$, where $\varphi: E_{i} \rightarrow F_{j}$ is the surjective mapping defined by $\varphi\left(x_{k}\right)=y_{k}$ for all $k \in\{1, \ldots, r\}$, and
(ii) $E_{\varphi^{\prime} j}$ if $\left\{y_{1}, \ldots, y_{r}\right\}=F_{j} \in \mathscr{E}_{2}$ and $\mathscr{E}_{1} \ni E_{i} \subseteq\left\{x_{1}, \ldots, x_{r}\right\} \subseteq E_{i}^{r}$, where $\varphi^{\prime}: F_{j} \rightarrow E_{i}$ is the surjective mapping defined by $\varphi^{\prime}\left(y_{k}\right)=x_{k}$ for all $k \in\{1, \ldots, r\}$,
where $X^{r}$ denotes a family of elements of a set $X$, that contains each element of $X$ with multiplicity $r$. Notice, if there exists no edge of the form $E_{i \varphi}$, all edges of $H$ are of the form $E_{\varphi^{\prime} j}$ and vice

## 2 Hypergraph Products

versa. With this notations, for the projections $p_{1}$ and $p_{2}$ of a product hypergraph $H=H_{1} \hat{\times} H_{2}$ into its factors $H_{1}$ and $H_{2}$, respectively, holds:

$$
p_{1}\left(E_{i \varphi}\right)=E_{i} \in \mathscr{E}\left(H_{1}\right) \quad \text { and } \quad p_{2}\left(E_{i \varphi}\right)=\varphi\left(E_{i}\right)=F_{j} \in \mathscr{E}\left(H_{2}\right),
$$

since $\varphi: E_{i} \rightarrow F_{j}$ is surjective, and

$$
p_{2}\left(E_{\varphi^{\prime} j}\right)=F_{j} \in \mathscr{E}\left(H_{2}\right) \quad \text { and } \quad p_{1}\left(E_{\varphi^{\prime} j}\right)=\varphi^{\prime}\left(F_{j}\right)=E_{i} \in \mathscr{E}\left(H_{1}\right),
$$

since $\varphi^{\prime}: F_{j} \rightarrow E_{i}$ is surjective. Hence, $p_{1}$ and $p_{2}$ are homomorphisms.
We can state:
For two hypergraphs $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ a subset $E \subseteq V_{1} \times V_{2}$ of the Cartesian product of their vertex sets is an edge in their direct product $\hat{\chi}, H=H_{1} \hat{\times} H_{2}$ if and only if
(i) $p_{1}(E)$ is an edge in $H_{1}$ and
(ii) $p_{2}(E)$ is an edge in $H_{2}$ and
(iii) $|E|=\max \left\{\left|p_{1}(E)\right|,\left|p_{2}(E)\right|\right\}$.

If we restrict this product to $r$-uniform hypergraphs, we get the product defined by Equation (2.3), i.e,

$$
\mathscr{E}\left(H_{1} \hat{\otimes} H_{2}\right):=\left\{\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\} \mid\left\{x_{1}, \ldots, x_{r}\right\} \in \mathscr{E}\left(H_{1}\right),\left\{y_{1}, \ldots, y_{r}\right\} \in \mathscr{E}\left(H_{2}\right)\right\}
$$

for $r$-uniform hypergraphs $H_{1}$ and $H_{2}$. Thus, this product coincides with the direct graph product in the class of simple graphs.
We have:

$$
r\left(H_{1} \hat{\times} H_{2}\right)=\max \left\{r\left(H_{1}\right), r\left(H_{2}\right)\right\}
$$

and

$$
s\left(H_{1} \hat{\times} H_{2}\right)=\max \left\{s\left(H_{1}\right), s\left(H_{2}\right)\right\}
$$

where $r(H)$ and $s(H)$ denote the rank and the anti-rank, respectively of a hypergraph $H$. From analogous considerations as for the direct product $\check{x}$, we can state:

Lemma 2.10. The direct product $\hat{\times}$ is associative, commutative and distributive with respect to the disjoint union.

## 2 Hypergraph Products

The one vertex hypergraph with a loop, $\mathcal{L} K_{1}$ is a unit for the direct product $\hat{\times}$ in the class of hypergraphs with loops. In the class of simple hypergraphs, this product has no unit. The direct product $\hat{x}$ of two connected hypergraphs need not to be connected, since it need not to be connected in the class of graphs. It remains to show the following property:

Lemma 2.11. The direct product $\hat{\times}, H=\hat{X}_{i=1}^{n} H_{i}$ of simple hypergraphs $H_{i}$ is simple
Proof. Because of associativity and commutativity of the direct product $\hat{x}$, it suffices to prove the assertion for $n=2$. Therefore, let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ be two simple hypergraphs and suppose $H=H_{1} \hat{\times} H_{2}$ is not simple. Then several cases can occur.

Suppose $H$ contains at least one loop $\{(x, y)\}$. Then, it follows, $\{x\}$ is an edge in $H_{1}$, i.e., a loop and $\{y\}$ is a loop in $H_{2}$, contradicting the fact, that $H_{1}$ and $H_{2}$ are simple. Thus, $|E| \geq 2$ for all $E \in \mathscr{E}(H)$.

Now assume there is an edge $E_{i_{1} \varphi_{1}}$ that is contained in an edge $E_{i_{2} \varphi_{2}}$, where $E_{i_{1} \varphi_{1}}=$ $\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$, such that $\left\{x_{1}, \ldots, x_{r}\right\}=E_{i_{1}} \in \mathscr{E}_{1}$ and $\varphi_{1}: E_{i_{1}} \rightarrow F_{j_{1}}$ through $x_{k} \mapsto y_{k}$, for all $k \in\{1, \ldots, r\}$ and $E_{i_{2} \varphi_{2}}=\left\{\left(x_{1}^{\prime}, y_{1}^{\prime}\right), \ldots,\left(x_{s}^{\prime}, y_{s}^{\prime}\right)\right\}, s \geq r$ such that $\left\{x_{1}^{\prime}, \ldots, x_{s}^{\prime}\right\}=E_{i_{2}} \in \mathscr{E}_{1}$ and $\varphi_{2}: E_{i_{2}} \rightarrow F_{j_{2}}$ through $x_{k}^{\prime} \mapsto y_{k}^{\prime}$, for all $k \in\{1, \ldots, s\}$. If there is no edge of the form $E_{i \varphi}$ contained in $H$, we consider the hypergraph $H_{2} \hat{\times} H_{1}$. Then it immediately follows

$$
\begin{align*}
E_{i_{1}}= & \left\{x_{1}, \ldots, x_{r}\right\} \subseteq\left\{x_{1}^{\prime}, \ldots, x_{s}^{\prime}\right\}=E_{i_{2}}  \tag{2.4}\\
& \left\{y_{1}, \ldots, y_{r}\right\} \subseteq\left\{y_{1}^{\prime}, \ldots, y_{s}^{\prime}\right\} \tag{2.5}
\end{align*}
$$

Equation (2.4) implies $i_{1}=i_{2}$, since $H_{1}$ is simple. On the other hand $\varphi_{1}(x)=\varphi_{2}(x)$ must hold for all $x \in E_{i_{1}}=E_{i_{2}}$, hence $\varphi_{1}=\varphi_{2}$. Thus, we can conclude that $E_{i_{1} \varphi_{1}} \subseteq E_{i_{2} \varphi_{2}}$ implies $\left(i_{1} \varphi_{1}\right)=$ $\left(i_{2} \varphi_{2}\right)$.
The fact that $E_{\varphi_{1}^{\prime} j_{1}} \subseteq E_{\varphi_{2}^{\prime} j_{2}}$ implies $\left(\varphi_{1}^{\prime} j_{1}\right)=\left(\varphi_{2}^{\prime} j_{2}\right)$ is shown analogously.
Now suppose we have $E_{i \varphi} \subseteq E_{\varphi^{\prime} j}$, where $E_{i \varphi}=\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$, such that $\left\{x_{1}, \ldots, x_{r}\right\}=$ $E_{i} \in \mathscr{E}_{1}$ and $\varphi: E_{i} \rightarrow F_{m}, F_{m} \in \mathscr{E}_{2}$, through $x_{k} \mapsto y_{k}$, for all $k \in\{1, \ldots, r\}$, respectively $E_{\varphi^{\prime} j}=$ $\left\{\left(x_{1}^{\prime}, y_{1}^{\prime}\right), \ldots,\left(x_{s}^{\prime}, y_{s}^{\prime}\right)\right\}, s \geq r$ such that $\left\{y_{s}^{\prime}, \ldots, y_{s}^{\prime}\right\}=F_{j} \in \mathscr{E}_{2}$ and $\varphi^{\prime}: F_{j} \rightarrow E_{l}, E_{l} \in \mathscr{E}_{1}$, through $y_{k}^{\prime} \mapsto x_{k}^{\prime}$, for all $k \in\{1, \ldots, s\}$. Notice that $F_{m} \subseteq\left\{y_{1}, \ldots, y_{r}\right\} \subseteq F_{m}^{r}$ and $E_{l} \subseteq\left\{x_{1}^{\prime}, \ldots, x_{s}^{\prime}\right\} \subseteq E_{l}^{s}$, respectively. It follows

$$
\begin{align*}
& E_{i}=\left\{x_{1}, \ldots, x_{r}\right\} \subseteq\left\{x_{1}^{\prime}, \ldots, x_{s}^{\prime}\right\} \subseteq E_{l}^{s}  \tag{2.6}\\
& F_{m} \subseteq\left\{y_{1}, \ldots, y_{r}\right\} \subseteq\left\{y_{1}^{\prime}, \ldots, y_{s}^{\prime}\right\}=F_{j} \tag{2.7}
\end{align*}
$$

Equation (2.7) implies $m=j$, since $H_{2}$ is simple. In particular holds $F_{m}=\left\{y_{1}, \ldots, y_{r}\right\}$, hence $y_{k} \neq y_{k^{\prime}}$, and therefore $\varphi\left(x_{k}\right) \neq \varphi\left(x_{k}^{\prime}\right)$ for all $k \neq k^{\prime}$ and as $x_{k} \neq x_{k}^{\prime}$ for all $k \neq k^{\prime}$ we can conclude

## 2 Hypergraph Products

that $\varphi$ is injective, thus bijective. We can now define $\varphi^{-1}: F_{m}=F_{j} \rightarrow E_{i}$ through $\varphi^{-1}\left(y_{k}\right)=x_{k}$ for all $k \in\{1, \ldots, r\}$ and denote $E_{i \varphi}$ by $E_{\varphi^{-1} j}$. On the other hand $\varphi^{\prime}(y)=\varphi^{-1}(y)$ must hold for all $y \in F_{m}=F_{j}$, hence $\varphi^{\prime}=\varphi^{-1}$, and therefore $E_{i \varphi} \subseteq E_{\varphi^{\prime} j}$ implies $(i \varphi)=\left(\varphi^{-1} j\right)=\left(\varphi^{\prime} j\right)$.
The fact that $E_{\varphi^{\prime} j} \subseteq E_{i \varphi}$ implies $\left(\varphi^{\prime} j\right)=(i \varphi)$ is shown analogously as well.
Thus $H$ is simple.

As mentioned, the restriction of the direct product $\hat{x}$ to simple graphs is the direct graph product. Moreover, the restriction of this product to graphs coincides with the direct graph product in general, also in the class of not necessarily simple graphs with loops.

Since this product is associative and commutative, the direct product $\hat{x}$ of arbitrary many factors $H=\hat{x}_{i=1}^{n} H_{i}$ is well defined, and we can state:
$E \subseteq V(H)$ is an edge in $H$ if and only if
(1) $p_{i}(E) \in \mathscr{E}\left(H_{i}\right)$ for all $i \in\{1, \ldots, n\}$ and
(2) $|E|=\left|p_{j}(E)\right|$ for a $j \in\{1, \ldots, n\}$.

Notice, that item (2) implies $|E|=\max _{j}\left|p_{j}(E)\right|$.

### 2.2.2 A Direct Product that does not preserve Rank

For the sake of completeness, we want to introduce a hypergraph product here, whose restriction on 2-uniform hypergraphs coincides with the direct graph product, but which does not preserve $r$-uniformity in general.

For two hypergraphs $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$, we define their direct product $\tilde{x}$ by the edge set

$$
\mathscr{E}\left(H_{1} \tilde{\times} H_{2}\right):=\left\{\{(x, y)\} \cup\left(\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right) \mid(x, y) \in V(H) \text { and } x \in E_{i} \in \mathscr{E}_{1} ; y \in F_{j} \in \mathscr{E}_{2}\right\}
$$

Let an edge $E$ in $H=H_{1} \tilde{\times} H_{2}$ be denoted as

$$
E_{(x y),(i j)} \text { if } E=\{(x, y)\} \cup\left(\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right),
$$

where $E_{i} \in \mathscr{E}\left(H_{1}\right)$ and $F_{j} \in \mathscr{E}\left(H_{2}\right)$.

The direct product $\tilde{\times}$ is motivated by [31], where the authors introduced the concept of $\mathscr{N}$ systems. An $\mathscr{N}$-system $(X, \mathscr{N})$ consists of a nonempty finite set $X$ and a system $\mathscr{N}$ that associates to each $x \in X$ a collection $\mathscr{N}(x)=\left\{N^{1}(x), \ldots, N^{d(x)}(x)\right\}$ of subsets $N^{i}(x)$ of $X$ that

## 2 Hypergraph Products

contain $x$. The collection $\mathscr{N}(x)$ is then called the neighborhood of $x$. The direct product $(X, \mathscr{N})=\left(X_{1}, \mathscr{N}_{1}\right) \times\left(X_{2}, \mathscr{N}_{2}\right)$ of two $\mathscr{N}$-systems $\left(X_{1}, \mathscr{N}_{1}\right)$ and $\left(X_{2}, \mathscr{N}_{2}\right)$ is defined by
(1) $X=X_{1} \times X_{2}$
(2) The neighborhoods $\mathscr{N}\left(\left(x_{1}, x_{2}\right)\right)$ are the sets $\left\{N^{\prime} \times N^{\prime \prime} \mid N^{\prime} \in \mathscr{N}_{1}\left(x_{1}\right), N^{\prime \prime} \in \mathscr{N}_{2}\left(x_{2}\right)\right\}$.

A (simple) hypergraph $H=(V, \mathscr{E})$ can be described as an $\mathscr{N}$-system $(V, \mathscr{N})$ if we set

$$
\mathscr{N}(v)=\{E \in \mathscr{E} \mid v \in E\}
$$

for all $v \in V$.
Conversely, we can construct a system ( $V, \mathscr{N}^{o}$ ) of "open" neighborhoods by

$$
\mathscr{N}^{o}(v)=\{E \backslash\{v\} \mid v \in E \in \mathscr{E}\} .
$$

We define the product of such systems analogously. The represented hypergraph of a product of such $\mathscr{N}^{o}$-systems is then the direct product $\tilde{x}$ of the represented hypergraphs of the factors.

Remark 2.1. In the definition of the direct product $\tilde{x}$ the following case might occur:
Consider two hypergraphs $H_{1}$ and $H_{2}$ such that there are edges $E_{i} \in \mathscr{E}\left(H_{1}\right)$ and $F_{j} \in \mathscr{E}\left(H_{2}\right)$, such that $E_{i}=\{x, a\}$ and $F_{j}=\{y, b\}$. For the product $H=H_{1} \tilde{\times} H_{2}$ holds:

$$
\begin{aligned}
\mathscr{E}(H) \ni E_{(x y),(i j)} & =\{(x, y)\} \cup\left(\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right) \\
& =\{(a, b)\} \cup\left(\left(E_{i} \backslash\{a\}\right) \times\left(F_{j} \backslash\{b\}\right)\right)=E_{(a b),(i j)} \in \mathscr{E}(H)
\end{aligned}
$$

That is, we might get some multiple edges in the product hypergraph. In this case, we will consider those edges as one single edge.

Conversely, this does not imply that we consider two edges $\{(x, y)\} \cup\left(\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right)$ and $\{(a, b)\} \cup\left(\left(E_{k} \backslash\{a\}\right) \times\left(F_{l} \backslash\{b\}\right)\right) \in \mathscr{E}(H)$, with $E_{i}=\{x, a\}, E_{k}=\{x, a\} \in \mathscr{E}\left(H_{1}\right)$ and $F_{j}=\{y, b\}, F_{l}=\{y, b\} \in \mathscr{E}\left(H_{2}\right)$, as one single edge if $i \neq k$ or $j \neq l$, i.e., in the case that $H_{1}$ or $\mathrm{H}_{2}$ are non simple hypergraphs.

Figure 2.7 shows the direct product $\tilde{\chi}$ of two hypergraphs, both consisting of a single edge with three vertices. As this product is horrible to visualize, two hypergraphs $H_{1}$ and $H_{2}$ are depicted, whose union of the edge sets are the edges of the product hypergraph $H$.

## 2 Hypergraph Products

Figure 2.7: Direct product $\tilde{\times}, H=E_{3} \tilde{\times} E_{3}$ with edge set $\mathscr{E}(H)=\mathscr{E}\left(H_{1}\right) \cup \mathscr{E}\left(H_{2}\right)$

For the projections $p_{1}$ and $p_{2}$ of a product hypergraph $H=H_{1} \tilde{\times} H_{2}$ into its factors $H_{1}$ and $H_{2}$, respectively, holds:

$$
\begin{aligned}
& p_{1}\left(E_{(x y),(i j)}\right)=\left\{p_{1}((x, y))\right\} \cup p_{1}\left(\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right)=\{x\} \cup\left(E_{i} \backslash\{x\}\right)=E_{i} \in \mathscr{E}\left(H_{1}\right), \\
& p_{2}\left(E_{(x y),(i j)}\right)=\left\{p_{2}((x, y))\right\} \cup p_{2}\left(\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)=\{y\} \cup\left(F_{j} \backslash\{y\}\right)=F_{j} \in \mathscr{E}\left(H_{2}\right) .\right.
\end{aligned}
$$

Thus, they are homomorphisms.
If we restrict the definition of this product to 2-uniform hypergraphs, i.e. simple graphs, we have: $E \subseteq V\left(G_{1} \tilde{\times} G_{2}\right)$ is an edge in $G_{1} \tilde{\times} G_{2}$ iff $E=\left\{(x, y)\left(x^{\prime}, y^{\prime}\right)\right\}$ and $\left\{x, x^{\prime}\right\}$ is an edge in $G_{1}$ and $\left\{y, y^{\prime}\right\}$ is an edge in $G_{2}$. That is exactly the direct graph product.

For the direct product $\tilde{\times}$ we have:

$$
r\left(H_{1} \tilde{\times} H_{2}\right)=\left(r\left(H_{1}\right)-1\right)\left(r\left(H_{2}\right)-1\right)+1
$$

and

$$
s\left(H_{1} \tilde{\times} H_{2}\right)=\left(s\left(H_{1}\right)-1\right)\left(s\left(H_{2}\right)-1\right)+1
$$

## 2 Hypergraph Products

where $r(H)$ and $s(H)$ denote the rank and the anti-rank, respectively of a hypergraph $H$. Thus the (anti-)rank of a product might not be the (anti-)rank of one of its factors in general.

Lemma 2.12. The direct product $\tilde{x}$ is associative.
Proof. Let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right), H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ and $H_{3}=\left(V_{3}, \mathscr{E}_{3}\right)$ be hypergraphs. As before we need to show that the mapping $\psi: V\left(\left(H_{1} \tilde{\times} H_{2}\right) \tilde{\times} H_{3}\right) \rightarrow V\left(H_{1} \tilde{\times}\left(H_{2} \tilde{\times} H_{3}\right)\right)$ defined by $((x, y) z) \mapsto$ $(x,(y, z))$ is an isomorphism. There is nothing to show about bijectivity. It remains to show that for a subset $E \subseteq V\left(\left(H_{1} \tilde{\times} H_{2}\right) \tilde{\times} H_{3}\right), E$ is an edge in $\left(H_{1} \tilde{\times} H_{2}\right) \tilde{\times} H_{3}$, if and only if $\psi E$ is an edge in $H_{1} \tilde{\times}\left(H_{2} \tilde{\times} H_{3}\right)$. First, we will examine, how an edge in $\left(H_{1} \tilde{\times} H_{2}\right) \tilde{\times} H_{3}$ and $H_{1} \tilde{\times}\left(H_{2} \tilde{\times} H_{3}\right)$, respectively, look like. Recall that an edge $E^{\prime}$ of $H_{1} \tilde{\times} H_{2}$ must be of the form $E^{\prime}=\{(x, y)\} \cup\left(\left(D_{i} \backslash\{x\}\right) \times\left(E_{j} \backslash\{y\}\right)\right)$ where $x \in D_{i} \in \mathscr{E}_{1}$ and $y \in E_{j} \in \mathscr{E}_{2}$. Thus, we have $E \subseteq V\left(\left(H_{1} \tilde{\times} H_{2}\right) \tilde{\times} H_{3}\right)$ is an edge in $\left(H_{1} \tilde{\times} H_{2}\right) \tilde{\times} H_{3}$, iff

$$
\begin{align*}
E & =\{(w, z)\} \cup\left[\left(E^{\prime} \backslash\{w\}\right) \times\left(F_{k} \backslash\{z\}\right)\right] \\
& =\{((x, y), z)\} \cup\left[\left[\left(\{(x, y)\} \cup\left(\left(D_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right)\right) \backslash\{(x, y)\}\right] \times\left[F_{k} \backslash\{z\}\right]\right] \\
& =\{((x, y), z)\} \cup\left[\left[\left(D_{i} \backslash\{x\}\right) \times\left(E_{j} \backslash\{y\}\right)\right] \times\left[F_{k} \backslash\{z\}\right]\right], \tag{2.8}
\end{align*}
$$

where $w=(x, y) \in V_{1} \times V_{2}$ and $z \in V_{3}$, and $D_{i}, E_{j}$ and $F_{k}$ are edges in $\mathscr{E}_{1}, \mathscr{E}_{2}$ and $\mathscr{E}_{3}$, respectively, such that $x \in D_{i}, y \in E_{j}$ and $z \in F_{k}$.
On the other hand we have $F \subseteq V\left(H_{1} \tilde{\times}\left(H_{2} \tilde{\times} H_{3}\right)\right)$ is an edge in $H_{1} \tilde{\times}\left(H_{2} \tilde{\times} H_{3}\right)$, iff

$$
\begin{align*}
F & =\{(x, v)\} \cup\left[\left(D_{i} \backslash\{x\}\right) \times\left(F^{\prime} \backslash\{v\}\right)\right] \\
& =\{(x,(y, z))\} \cup\left[\left[D_{i} \backslash\{x\}\right] \times\left[\left(\{(y, z)\} \cup\left(\left(E_{j} \backslash\{y\}\right) \times\left(F_{k} \backslash\{z\}\right)\right)\right) \backslash\{(y, z)\}\right]\right] \\
& =\{(x,(y, z))\} \cup\left[\left[D_{i} \backslash\{x\}\right] \times\left[\left(E_{j} \backslash\{y\}\right) \times\left(F_{k} \backslash\{z\}\right)\right]\right], \tag{2.9}
\end{align*}
$$

where $F^{\prime}=\{(y, z)\} \cup\left(\left(E_{j} \backslash\{y\}\right) \times\left(F_{k} \backslash\{z\}\right)\right)$ is an edge in $H_{2} \tilde{\times} H_{3}, v=(y, z) \in V_{2} \times V_{3}$ and $D_{i}, E_{j}$ and $F_{k}$ are as in Equation (2.8).
We observe, that whenever $E \in \mathscr{E}\left(\left(H_{1} \tilde{\times} H_{2}\right) \tilde{\times} H_{3}\right)$, then it has the form as in Equation (2.8) and for its image $\psi(E)$ we have $\psi(E)=F \in \mathscr{E}\left(H_{1} \tilde{\times}\left(H_{2} \tilde{\times} H_{3}\right)\right)$.
Conversely, an edge $F$ of $H_{1} \tilde{\times}\left(H_{2} \tilde{\times} H_{3}\right)$ must have the form as in Equation (2.9), and if we set $F:=\psi(E)$, its preimage $E$ is an edge in $\left(H_{1} \tilde{\times} H_{2}\right) \tilde{\times} H_{3}$.
Therefore the mapping $\psi$ is an isomorphism and the assertion is true.

Lemma 2.13. The direct product $\tilde{x}$ is commutative.

## 2 Hypergraph Products

Proof. Let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ be two hypergraphs. We need to show, the mapping $\psi: V\left(H_{1} \tilde{\times} H_{2}\right) \rightarrow V\left(H_{2} \tilde{\times} H_{1}\right)$ defined by $(x, y) \mapsto(y, x)$ for $x \in V_{1}, y \in V_{2}$ is an isomorphism. For a subset $E$ of $V\left(H_{1} \tilde{\times} H_{2}\right)=V_{1} \times V_{2}, E$ is an edge in $H_{1} \times H_{2}$ if and only if $E=\{(x, y)\} \cup$ $\left(\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right)$, for $x \in E_{i} \in \mathscr{E}_{1}$ and $y \in F_{j} \in \mathscr{E}_{2}$.
This is equivalent to $\psi(E)=\{(y, x)\} \cup\left(\left(F_{j} \backslash\{y\}\right) \times\left(E_{i} \backslash\{x\}\right)\right)$. Hence, $E \in \mathscr{E}\left(H_{1} \tilde{\times} H_{2}\right)$ if and only if $\psi(E)$ is an edge in $H_{2} \tilde{\times} H_{1}$.

Lemma 2.14. The direct product $\tilde{\times}$ is left and right distributive together with the disjoint union as addition.

Proof. Let $H_{1}, H_{2}$ and $H_{3}$ be hypergraphs and furthermore, let $H_{2}$ and $H_{3}$ be vertex-disjoint. Then we have for the edge set of $H_{1} \tilde{\times}\left(H_{2}+H_{3}\right)$ :

$$
\begin{align*}
\mathscr{E}\left(H_{1} \tilde{\times}\left(H_{2}+H_{3}\right)\right)= & \left\{\{(x, y)\} \cup[(E \backslash\{x\}) \times(F \backslash\{y\})] \mid x \in E, E \in \mathscr{E}_{1} ; y \in F, F \in \mathscr{E}_{2} \cup \mathscr{E}_{3}\right\} \\
= & \left\{\{(x, y)\} \cup[(E \backslash\{x\}) \times(F \backslash\{y\})] \mid x \in E, E \in \mathscr{E}_{1} ; y \in F, F \in \mathscr{E}_{2}\right\} \\
& \cup\left\{\{(x, y)\} \cup[(E \backslash\{x\}) \times(F \backslash\{y\})] \mid x \in E, E \in \mathscr{E}_{1} ; y \in F, F \in \mathscr{E}_{3}\right\} \\
= & \mathscr{E}\left(H_{1} \tilde{\times} H_{2}\right) \cup \mathscr{E}\left(H_{1} \tilde{\times} H_{3}\right) \\
= & \mathscr{E}\left(\left(H_{1} \tilde{\times} H_{2}\right)+\left(H_{1} \tilde{\times} H_{3}\right)\right) . \tag{2.10}
\end{align*}
$$

With the same arguments as in Equation (2.1) we can conclude $V\left(H_{1} \tilde{\times}\left(H_{2}+H_{3}\right)\right)=$ $V\left(\left(H_{1} \tilde{\times} H_{2}\right)+\left(H_{1} \tilde{\times} H_{3}\right)\right)$ and hence, it follows

$$
H_{1} \tilde{\times}\left(H_{2}+H_{3}\right)=\left(H_{1} \tilde{\times} H_{2}\right)+\left(H_{1} \tilde{\times} H_{3}\right) .
$$

Analogously, it is shown

$$
\left(H_{1}+H_{2}\right) \tilde{\times} H_{3}=\left(H_{1} \tilde{\times} H_{3}\right)+\left(H_{2} \tilde{\times} H_{3}\right)
$$

for vertex-disjoint $H_{1}$ and $H_{2}$.

Next, we will examine on which conditions the direct product $\tilde{x}$ is a simple hypergraph.
Lemma 2.15. The direct product $\tilde{\chi}, H=\tilde{\chi}_{i=1}^{n} H_{i}$, of simple hypergraphs $H_{i}$ is simple.

Proof. Because of associativity and commutativity of the direct product $\tilde{x}$, it suffices to prove the assertion for $n=2$. Therefore, let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ be two simple hypergraphs and suppose $H=H_{1} \tilde{\times} H_{2}$ is not simple.
Assume first $H$ contains at least one loop $\{(x, y)\}$. Then, $\{(x, y)\}=\left\{\left(x^{\prime}, y^{\prime}\right)\right\} \cup\left[\left(E \backslash\left\{x^{\prime}\right\}\right) \times\right.$ $\left.\left(F \backslash\left\{y^{\prime}\right\}\right)\right]$ holds for an $x^{\prime} \in E \in \mathscr{E}_{1}$ and an $y^{\prime} \in F \in \mathscr{E}_{2}$. It follows $x=x^{\prime}$ and $y=y^{\prime}$ and $\left(E \backslash\left\{x^{\prime}\right\}\right) \times\left(F \backslash\left\{y^{\prime}\right\}\right)=\emptyset$. Hence, $E \backslash\left\{x^{\prime}\right\}=\emptyset$ or $F \backslash\left\{y^{\prime}\right\}=\emptyset$ must hold. We conclude that $E=\{x\}$ is an edge in $H_{1}$, i.e., a loop, or $F=\{y\}$ is a loop in $H_{2}$. Both contradicts the fact, that $H_{1}$ and $H_{2}$ are simple. Thus, $|E| \geq 2$ for all $E \in \mathscr{E}(H)$.
Now suppose $E_{(x y),(i j)} \subseteq E_{\left(x^{\prime} y^{\prime}\right),\left(i^{\prime} j^{\prime}\right),}$, i.e.

$$
\begin{equation*}
\{(x, y)\} \cup\left[\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right] \subseteq\left\{\left(x^{\prime}, y^{\prime}\right)\right\} \cup\left[\left(E_{i^{\prime}} \backslash\left\{x^{\prime}\right\}\right) \times\left(F_{j^{\prime}} \backslash\left\{y^{\prime}\right\}\right)\right] \tag{2.11}
\end{equation*}
$$

Then it immediately follows

$$
\begin{equation*}
(x, y) \in\left\{\left(x^{\prime}, y^{\prime}\right)\right\} \cup\left[\left(E_{i^{\prime}} \backslash\left\{x^{\prime}\right\}\right) \times\left(F_{j^{\prime}} \backslash\left\{y^{\prime}\right\}\right)\right] \subseteq E_{i^{\prime}} \times F_{j^{\prime}} \tag{2.12}
\end{equation*}
$$

and hence

$$
\begin{equation*}
x \in E_{i^{\prime}} \quad \text { and } \quad y \in F_{j^{\prime}} . \tag{2.13}
\end{equation*}
$$

and therefore we have

$$
\begin{equation*}
E_{i} \times F_{j} \subseteq E_{i^{\prime}} \times F_{j^{\prime}}, \tag{2.14}
\end{equation*}
$$

thus

$$
\begin{equation*}
E_{i} \subseteq E_{i^{\prime}} \quad \text { and } \quad F_{j} \subseteq F_{j^{\prime}} \tag{2.15}
\end{equation*}
$$

and since $H_{1}$ and $H_{2}$ are both simple, it follows

$$
\begin{equation*}
i=i^{\prime} \quad \text { as well as } \quad j=j^{\prime} \tag{2.16}
\end{equation*}
$$

It remains to show that $(x, y)=\left(x^{\prime}, y^{\prime}\right)$. We will prove this indirect. Assume $(x, y) \neq\left(x^{\prime}, y^{\prime}\right)$. Now from (2.11) and (2.16) we have

$$
\begin{equation*}
\underbrace{\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)}_{=: X} \subseteq \underbrace{\left\{\left(x^{\prime}, y^{\prime}\right)\right\} \cup\left[\left(E_{i} \backslash\left\{x^{\prime}\right\}\right) \times\left(F_{j} \backslash\left\{y^{\prime}\right\}\right)\right]}_{=: Y} \tag{2.17}
\end{equation*}
$$

## 2 Hypergraph Products

If we compute the intersection of these two sets we get

$$
\begin{align*}
A:= & {\left[\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right] \cap\left[\left\{\left(x^{\prime}, y^{\prime}\right)\right\} \cup\left[\left(E_{i} \backslash\left\{x^{\prime}\right\}\right) \times\left(F_{j} \backslash\left\{y^{\prime}\right\}\right)\right]\right] } \\
= & \underbrace{\left[\left[\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right] \cap\left\{\left(x^{\prime}, y^{\prime}\right)\right\}\right]}_{=: B} \\
& \cup \underbrace{\left.\cup\left[\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)\right] \cap\left[\left(E_{i} \backslash\left\{x^{\prime}\right\}\right) \times\left(F_{j} \backslash\left\{y^{\prime}\right\}\right)\right]\right]}_{=: C} \tag{2.18}
\end{align*}
$$

For short, it holds

$$
\begin{equation*}
X \cap Y=A=B \cup C \stackrel{(2.17)}{=} X \tag{2.19}
\end{equation*}
$$

Now we have to distinguish several cases: First suppose $x \neq x^{\prime}$ and $y=y^{\prime}$ Then it follows for the sets $B$ and $C$ in (2.18)

$$
\begin{align*}
& B=\emptyset \\
& C=\left(E_{i} \backslash\left\{x, x^{\prime}\right\}\right) \times\left(F_{j} \backslash\{y\}\right) \tag{2.20}
\end{align*}
$$

But Equation (2.19) implies

$$
\begin{equation*}
\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)=\left(E_{i} \backslash\left\{x, x^{\prime}\right\}\right) \times\left(F_{j} \backslash\{y\}\right) \tag{2.21}
\end{equation*}
$$

and hence in particular

$$
\begin{equation*}
E_{i} \backslash\{x\}=E_{i} \backslash\left\{x, x^{\prime}\right\} \tag{2.22}
\end{equation*}
$$

which is a contradiction, so the case $x^{\prime} \neq x$ and $y=y^{\prime}$ cannot occur. The case $x=x^{\prime}$ and $y \neq y^{\prime}$ leads analogously to a contradiction.
Now suppose $x \neq x^{\prime}$ and $y \neq y^{\prime}$. We then have for $B$ and $C$ in (2.18):

$$
\begin{align*}
& B=\left\{\left(x^{\prime}, y^{\prime}\right)\right\} \\
& C=\left(E_{i} \backslash\left\{x, x^{\prime}\right\}\right) \times\left(F_{j} \backslash\left\{y, y^{\prime}\right\}\right) \tag{2.23}
\end{align*}
$$

And again from (2.19)

$$
\begin{equation*}
\left(E_{i} \backslash\{x\}\right) \times\left(F_{j} \backslash\{y\}\right)=\left\{\left(x^{\prime}, y^{\prime}\right)\right\} \cup\left[\left(E_{i} \backslash\left\{x, x^{\prime}\right\}\right) \times\left(F_{j} \backslash\left\{y, y^{\prime}\right\}\right)\right] \tag{2.24}
\end{equation*}
$$

must hold. But this can only be fulfilled if $E_{i}=\left\{x, x^{\prime}\right\}$ and $F_{j}=\left\{y, y^{\prime}\right\}$.
Together with Remark 2.1 we can conclude that $H$ is simple.

## 2 Hypergraph Products

The direct product $\tilde{\times}$ of arbitrary many hypergraphs $H=\tilde{X}_{i=1}^{n} H_{i}$ is well defined, since it is associative and commutative. Also the projections of a hypergraph product of arbitrary many hypergraphs into its factors are homomorphisms. However, the direct product $\tilde{\times}$ does not have a unit, neither in the class of simple hypergraphs, since the direct graph product has no unit in the class of simple graphs, nor in the class of non simple hypergraphs.

Example 2.4. Consider the (hyper)graphs $K_{2}=(\{a, b\},\{\{a, b\}\})$, consisting of two vertices and one single edge containing these vertices and $\mathcal{L} K_{1}=(\{x\},\{\{x\}\})$, respectively. Then:

$$
V\left(K_{2} \tilde{\times} \mathcal{L} K_{1}\right)=\{(a, x),(b, x)\}=V\left(K_{2} \times \mathcal{L} K_{1}\right)
$$

but

$$
\mathscr{E}\left(K_{2} \tilde{\times} \mathcal{L} K_{1}\right)=\{\{(a, x)\},\{(b, x)\}\} \neq\{\{(a, x),(b, x)\}\}=\mathscr{E}\left(K_{2} \times \mathcal{L} K_{1}\right)
$$

where $\tilde{\times}$ denotes the direct product $\tilde{x}$ of hypergraphs, and $\times$ denotes the (usual) direct graph product. Thus, $K_{2} \tilde{\times} \mathcal{L} K_{1} \neq K_{2} \times \mathcal{L} K_{1}$.

Hence, $\mathcal{L} K_{1}$ is not a unit with respect to the direct product $\tilde{\times}$, and the direct product $\tilde{\times}$ does not coincide with the direct graph product in the class of graphs with loops.
For this reasons we will not consider this product further.

## Summary

Three hypergraph products were defined in this section. The direct product $\check{x}$, the direct product $\hat{x}$ and the direct product $\tilde{x}$. For all these products, the following results hold:

1. The restriction of these products on simple graphs is the direct graph product.
2. Associativity.
3. Commutativity.
4. Distributivity with respect to the disjoint union.
5. The product of two simple hypergraphs is simple.

Furthermore, for the direct product $\hat{x}$ and the direct product $\tilde{x}$ holds:
6. The projections of a product hypergraph onto its factors are homomorphisms.

## 2 Hypergraph Products

And in addition, the direct product $\hat{x}$ coincides with the direct graph product in the class of non simple graphs and graphs with loops as well.

Remark 2.2. In the following, we will refer to the direct product $\hat{x}$ as direct product, denoted by $\times$.

As an open problem, it remains to examine if the direct product has a unique prime factorization. But that would go beyond the scope of this thesis.

### 2.3 The Strong Product

In graph theory, the edge set of a strong product of two graphs is the union of the edge sets of their Cartesian and direct product. For hypergraphs, we will proceed in the same way.
With the direct products of the last section, there are three possible definitions of a strong hypergraph product, whose restrictions to simple graphs result in the strong graph product:
Let the edge set of a strong product $H=H_{1} \stackrel{*}{\boxtimes} H_{2}, *=\vee, \wedge, \sim$ of two hypergraphs $H_{1}, H_{2}$ be

$$
\mathscr{E}\left(H_{1} \stackrel{*}{\boxtimes} H_{2}\right)=\mathscr{E}\left(H_{1} \square H_{2}\right) \cup \mathscr{E}\left(H_{1} \stackrel{*}{\times} H_{2}\right),
$$

where $\mathscr{E}\left(H_{1} \stackrel{*}{\times} H_{2}\right)$ corresponds to the respective direct product from Section 2.2.
For the same reasons as in Section 2.2, the respective strong products resulting from the direct product $\tilde{x}$ and the direct product $\check{x}$ do not coincide with the strong graph product if we admit loops. Therefore, we will only consider the strong product which belongs to the direct product, i.e., the direct product $\hat{x}$.

We define the strong product $H=H_{1} \boxtimes H_{2}$ of two hypergraphs $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ by the edge set

$$
\begin{equation*}
\mathscr{E}\left(H_{1} \boxtimes H_{2}\right)=\mathscr{E}\left(H_{1} \square H_{2}\right) \cup \mathscr{E}\left(H_{1} \times H_{2}\right), \tag{2.25}
\end{equation*}
$$

In other words, a subset $E=\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$ of the vertex set $V(H)=V_{1} \times V_{2}$ is an edge in $H=H_{1} \boxtimes H_{2}$ if and only if
(i) $\left\{x_{1}, \ldots, x_{r}\right\}$ is an edge in $\mathscr{E}\left(H_{1}\right)$ and $y_{1}=\ldots=y_{r}$, or
(ii) $\left\{y_{1}, \ldots, y_{r}\right\}$ is an edge in $\mathscr{E}\left(H_{2}\right)$ and $x_{1}=\ldots=x_{r}$, or
(iii) $\left\{x_{1}, \ldots, x_{r}\right\}$ is an edge in $H_{1}$ and there is an edge $F \in \mathscr{E}_{2}$ of $H_{2}$ such that $\left\{y_{1}, \ldots y_{r}\right\}$ is a family of elements of $F$, and $F \subseteq\left\{y_{1}, \ldots, y_{r}\right\}$, or

## 2 Hypergraph Products

(iv) $\left\{y_{1}, \ldots, y_{r}\right\}$ is an edge in $H_{2}$ and there is an edge $F \in \mathscr{E}_{1}$ of $H_{1}$ such that $\left\{x_{1}, \ldots x_{r}\right\}$ is a family of elements of $E$, and $E \subseteq\left\{x_{1}, \ldots, x_{r}\right\}$.

The projections $p_{1}$ and $p_{2}$ of a strong product $H=H_{1} \boxtimes H_{2}$ of two hypergraphs into its factors are weak homomorphisms, since edges included in the second term of the right hand side of Equation (2.25) are mapped into edges, and those included in the first term are mapped into edges or vertices.
We have for an edge $E \in \mathscr{E}(H)$ :

- $E$ is Cartesian if and only if

$$
\begin{aligned}
& \left|p_{1}(E)\right|=1 \text { and } p_{2}(E) \in \mathscr{E}\left(H_{2}\right) \text {, or } \\
& p_{1}(E) \in \mathscr{E}\left(H_{1}\right) \text { and }\left|p_{2}(E)\right|=1 \text { and }
\end{aligned}
$$

- $E$ is non-Cartesian if and only if

$$
p_{1}(E) \in \mathscr{E}\left(H_{1}\right), p_{2}(E) \in \mathscr{E}\left(H_{2}\right) \text { and }\left|p_{i}(E)\right|=|E| \text { for an } i \in\{1,2\} .
$$

Let a Cartesian edge $E=\left\{\left(x_{1}, y_{1}\right), \ldots,\left(x_{r}, y_{r}\right)\right\}$ in $H=H_{1} \boxtimes H_{2}$ be denoted by
(i) $E_{i y}$ if $E=E_{i} \times\{y\}$, where $\left\{x_{1}, \ldots, x_{r}\right\}=E_{i} \in \mathscr{E}\left(H_{1}\right)$ and $y_{1}=\ldots=y_{r}=y \in V\left(H_{2}\right)$, and
(ii) $E_{x j}$ if $E=\{x\} \times E_{j}$, where $x_{1}=\ldots=x_{r}=x \in V\left(H_{1}\right)$ and $\left\{y_{1}, \ldots, y_{r}\right\}=E_{j} \in \mathscr{E}\left(H_{2}\right)$ and a non-Cartesian edge by
(iii) $E_{i \varphi}$ if $\left\{x_{1}, \ldots, x_{r}\right\}=E_{i} \in \mathscr{E}_{1}$ and $\mathscr{E}_{2} \ni F_{j} \subseteq\left\{y_{1}, \ldots, y_{r}\right\} \subseteq F_{j}^{r}$, where $\varphi: E_{i} \rightarrow F_{j}$ is the surjective mapping defined by $\varphi\left(x_{k}\right)=y_{k}$ for all $k \in\{1, \ldots, r\}$, and
(iv) $E_{\varphi^{\prime} j}$ if $\left\{y_{1}, \ldots, y_{r}\right\}=F_{j} \in \mathscr{E}_{2}$ and $\mathscr{E}_{1} \ni E_{i} \subseteq\left\{x_{1}, \ldots, x_{r}\right\} \subseteq E_{i}^{r}$, where $\varphi^{\prime}: F_{j} \rightarrow E_{i}$ is the surjective mapping defined by $\varphi^{\prime}\left(y_{k}\right)=x_{k}$ for all $k \in\{1, \ldots, r\}$.

If $H_{i}, i \in\{1,2\}$ is not prime, i.e., $H_{i}=H_{i}^{\prime} \boxtimes H_{i}^{\prime \prime}$, then an edge $E \in \mathscr{E}(H)$ is Cartesian in $\left(H_{1}^{\prime} \boxtimes H_{1}^{\prime \prime}\right) \boxtimes H_{2}$ iff (i) holds or (ii) is fulfilled and $p_{1}(E)$ is Cartesian in $H_{1}^{\prime} \boxtimes H_{1}^{\prime \prime}$. Similar $E$ is Cartesian in $H_{1} \boxtimes\left(H_{2}^{\prime} \boxtimes H_{2}^{\prime \prime}\right)$ iff (i) is fulfilled and $p_{2}(E)$ is Cartesian in $H_{2}^{\prime} \boxtimes H_{2}^{\prime \prime}$ or (ii) holds. Otherwise, if the respective condition would be fulfilled, but $p_{i}(E)$ is non-Cartesian in $H_{i}^{\prime} \boxtimes H_{i}^{\prime \prime}$, then $E$ is non-Cartesian in $\left(H_{1}^{\prime} \boxtimes H_{1}^{\prime \prime}\right) \boxtimes H_{2}$ or $H_{1} \boxtimes\left(H_{2}^{\prime} \boxtimes H_{2}^{\prime \prime}\right)$, respectively.

In graph theory, the strong product can be seen as a special case of the direct one. There is no reason not to claim this for strong hypergraph products.

## 2 Hypergraph Products

Let $\mathcal{N} H$ denote the partial hypergraph of $H$ with edges $\mathscr{E}(\mathcal{N} H)=\{E \in \mathscr{E}(H)| | E \mid \geq 2\}$. On the other hand let $\mathcal{L} H^{\prime}$ denote the hypergraph, which arises from $H^{\prime}$ by assigning a loop to each vertex of $H^{\prime}$. For a hypergraph $H=(V, \mathscr{E})$ without loops we have $\mathscr{E}(\mathcal{L} H)=\mathscr{E} \cup\{\{v\} \mid v \in V\}$. Then for the strong and the direct product holds

$$
\begin{equation*}
H_{1} \boxtimes H_{2}=\mathcal{N}\left(\mathcal{L} H_{1} \times \mathcal{L} H_{2}\right) \tag{2.26}
\end{equation*}
$$

for hypergraphs $H_{1}, H_{2}$ without loops.

$E_{3} \boxtimes E_{3}$

Figure 2.8: Strong product $E_{3} \boxtimes E_{3}$, red Cartesian edges

Figure 2.8 shows the strong product of the hypergraph $E_{3}$, which consists of a single edge with three vertices, multiplied with itself. The Cartesian edges of this product are highlighted red.

Lemma 2.16. The strong product is associative
Proof. Let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right), H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ and $H_{3}=\left(V_{3}, \mathscr{E}_{3}\right)$ be hypergraphs. Again we have to show, that the bijective mapping $\psi: V\left(\left(H_{1} \boxtimes H_{2}\right) \boxtimes H_{3}\right) \rightarrow V\left(H_{1} \boxtimes\left(H_{2} \boxtimes H_{3}\right)\right)$, defined by $((x, y), z) \mapsto(x,(y, z))$ is an isomorphism.
In the following, let $p_{H_{i} \boxtimes H_{i+1}}$ denote the projection from $\left(H_{1} \boxtimes H_{2}\right) \boxtimes H_{3}$ into $H_{1} \boxtimes H_{2}$ for $i=1$ and from $H_{1} \boxtimes\left(H_{2} \boxtimes H_{3}\right)$ into $H_{2} \boxtimes H_{3}$ for $i=2$, respectively, whereas $p_{j}$ denotes the projection into $H_{j}$ for all $j \in\{1,2,3\}$.
Consider first a Cartesian edge $E$ of $\left(H_{1} \boxtimes H_{2}\right) \boxtimes H_{3}$. One observe that for $E$ one of the following cases must be fulfilled
(i) $p_{1}(E) \in \mathscr{E}_{1},\left|p_{1}(E)\right|=|E|$ and $\left|p_{2}(E)\right|=\left|p_{3}(E)\right|=1$, or

## 2 Hypergraph Products

(ii) $p_{2}(E) \in \mathscr{E}_{2},\left|p_{2}(E)\right|=|E|$ and $\left|p_{1}(E)\right|=\left|p_{3}(E)\right|=1$, or
(iii) $p_{3}(E) \in \mathscr{E}_{3},\left|p_{3}(E)\right|=|E|$ and $\left|p_{1}(E)\right|=\left|p_{2}(E)\right|=1$

But since $p_{i}(\psi(E))=p_{i}(E)$ for all $E \subseteq V\left(\left(H_{1} \boxtimes H_{2}\right) \boxtimes H_{3}\right)$ and all $i \in\{1,2,3\}$, as one can easily see, this is equivalent to $\psi(E)$ being a Cartesian edge in $H_{1} \boxtimes\left(H_{2} \boxtimes H_{3}\right)$.
Now let $E$ be non-Cartesian. Then one of the following must hold:
(i) $p_{H_{1} \boxtimes H_{2}}(E) \in \mathscr{E}\left(H_{1} \boxtimes H_{2}\right)$ and non-Cartesian, $\left|p_{H_{1} \boxtimes H_{2}}(E)\right|=|E|$ and $\left|p_{3}(E)\right|=1$, or
(ii) $p_{H_{1} \boxtimes H_{2}}(E) \in \mathscr{E}\left(H_{1} \boxtimes H_{2}\right), p_{3}(E) \in \mathscr{E}_{3}$ and $\left|p_{H_{1} \boxtimes H_{2}}(E)\right|=|E|$ or $\left|p_{3}(E)\right|=|E|$.

Then (i) is equivalent to $p_{1}(E) \in \mathscr{E}_{1}, p_{2}(E) \in \mathscr{E}_{2},\left|p_{i}(E)\right|=|E|$ for an $i \in\{1,2\}$ and $\left|p_{3}(E)=1\right|$. Condition (ii) is equivalent to the following:
(iia) $p_{i}(E) \in \mathscr{E}_{i}$ for $i=1,2,3$ and $\left|p_{j}(E)\right|=|E|$ for a $j \in\{1,2,3\}$, or
(iib) $p_{1}(E) \in \mathscr{E}_{1},\left|p_{2}(E)\right|=1, p_{3}(E) \in \mathscr{E}_{3}\left|p_{1}(E)\right|=|E|$ or $\left|p_{3}(E)\right|=|E|$, or
(iic) $\left|p_{1}(E)\right|=1, p_{2}(E) \in \mathscr{E}_{2}, p_{3}(E) \in \mathscr{E}_{3}\left|p_{2}(E)\right|=|E|$ or $\left|p_{3}(E)\right|=|E|$.
And again, since $p_{i}(\psi(E))=p_{i}(E)$ for all $E \subseteq V\left(\left(H_{1} \boxtimes H_{2}\right) \boxtimes H_{3}\right)$ and $i \in\{1,2,3\}$, it follows (iic) is equivalent to
(i') $\left|p_{1}(\psi(E))=1\right|, p_{H_{2} \boxtimes H_{3}}(\psi(E)) \in \mathscr{E}\left(H_{2} \boxtimes H_{3}\right)$ and non-Cartesian and $\left|p_{H_{2} \boxtimes H_{3}}(\psi(E))\right|=$ $|\psi(E)|$,
whereas conditions (i),(iia) and (iib) are equivalent to
(ii') $p_{1}(\psi(E)) \in \mathscr{E}_{1}, \quad p_{H_{2} \boxtimes H_{3}}(\psi(E)) \in \mathscr{E}\left(H_{2} \boxtimes H_{3}\right) \quad$ and $\quad\left|p_{1}(\psi(E))\right|=|\psi(E)| \quad$ or $\left|p_{H_{2} \boxtimes H_{3}}(\psi(E))\right|=|\psi(E)|$.

This is equivalent to $\psi(E)$ being a non-Cartesian edge in $H_{1} \boxtimes\left(H_{2} \boxtimes H_{3}\right)$.
Altogether we can state, $E$ is an edge in $\left(H_{1} \boxtimes H_{2}\right) \boxtimes H_{3}$ if and only if $\psi(E)$ is an edge in $H_{1} \boxtimes\left(H_{2} \boxtimes H_{3}\right)$. Hence $\left(H_{1} \boxtimes H_{2}\right) \boxtimes H_{3} \cong H_{1} \boxtimes\left(H_{2} \boxtimes H_{3}\right)$.

Because of the symmetry of the definition of the strong product, we can state:
Lemma 2.17. The strong product is commutative.
The strong product has $K_{1}$ as unit. From distributivity of the Cartesian and the strong product, respectively, together with the disjoint union we can infer:

## 2 Hypergraph Products

Lemma 2.18. The strong product is left and right distributive together with the disjoint union as addition.

Proof. Let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right), H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ and $H_{3}=\left(V_{3}, \mathscr{E}_{3}\right)$ be hypergraphs and let $H_{2}$ and $H_{3}$ be vertex-disjoint. Then the following holds

$$
\begin{aligned}
\mathscr{E}\left(H_{1} \boxtimes\left(H_{2}+H_{3}\right)\right) & =\mathscr{E}\left(H_{1} \square\left(H_{2}+H_{3}\right)\right) \cup \mathscr{E}\left(H_{1} \times\left(H_{2}+H_{3}\right)\right) \\
& =\mathscr{E}\left(H_{1} \square H_{2}\right) \cup \mathscr{E}\left(H_{1} \square H_{3}\right) \cup \mathscr{E}\left(H_{1} \times H_{2}\right) \cup \mathscr{E}\left(H_{1} \times H_{3}\right) \\
& =\mathscr{E}\left(H_{1} \boxtimes H_{2}\right) \cup \mathscr{E}\left(H_{1} \boxtimes H_{3}\right)=\mathscr{E}\left(H_{1} \boxtimes H_{2}+H_{1} \boxtimes H_{3}\right) .
\end{aligned}
$$

With the same arguments as in Equation (2.1) we can conclude $V\left(H_{1} \boxtimes\left(H_{2}+H_{3}\right)\right)=V\left(\left(H_{1} \boxtimes\right.\right.$ $\left.\left.H_{2}\right)+\left(H_{1} \boxtimes H_{3}\right)\right)$ and hence, it follows $H_{1} \boxtimes\left(H_{2}+H_{3}\right)=\left(H_{1} \boxtimes H_{2}\right)+\left(H_{1} \boxtimes H_{3}\right)$.
Analogously we can conclude $\left(H_{1}+H_{2}\right) \boxtimes H_{3}=\left(H_{1}+H_{3}\right) \boxtimes\left(H_{2}+H_{3}\right)$ for vertex disjoint hypergraphs $H_{1}$ and $H_{2}$.

Lemma 2.19. The strong product, $H=\boxtimes_{i=1}^{n} H_{i}$, of simple hypergraphs $H_{i}$ is simple.
Proof. Since the strong product is associative and commutative, it suffices to prove the assertion for $n=2$. Therefore, let $H_{1}=\left(V_{1}, \mathscr{E}_{1}\right)$ and $H_{2}=\left(V_{2}, \mathscr{E}_{2}\right)$ be two simple hypergraphs and consider their strong product $H=H_{1} \boxtimes H_{2}$. Due to the fact that the Cartesian product and the direct product of simple hypergraphs is simple, as shown in Lemma 2.5 and Lemma 2.11, respectively, it remains to show, that no Cartesian edge is contained in any non-Cartesian edge or vice versa.

We show first, that no Cartesian edge is contained in any non-Cartesian edge if the factors are simple.
Assume $E_{i y}=\bigcup_{x \in E_{i}}\{(x, y)\} \subseteq E_{j \varphi}=\bigcup_{x \in E_{j}}\{(x, \varphi(x))\}$, where $\varphi$ is a surjective mapping $\varphi$ : $E_{j} \rightarrow F_{k}$. It immediately follows $E_{i} \subseteq E_{j}$, which implies $i=j$, hence $\left|E_{i y}\right|=\left|E_{j \varphi}\right|$, and therefore we have $E_{i y}=E_{j \varphi}$ and thus $F_{j}=\{y\}$, which implies that $H_{2}$ is not simple.
Analogously, it is shown that the case $E_{x j} \subseteq E_{\varphi^{\prime} i}$ cannot occur if $H_{1}$ and $H_{2}$ are simple.
Now suppose $E_{i y}=\left\{\left(x_{1}, y\right), \ldots,\left(x_{r}, y\right)\right\} \subseteq E_{\varphi^{\prime} j}=\left\{\left(\varphi^{\prime}\left(y_{1}\right), y_{1}\right), \ldots,\left(\varphi^{\prime}\left(y_{s}\right), y_{s}\right)\right\}$ for $\mathscr{E}_{1} \ni E_{i}=$ $\left\{x_{1}, \ldots, x_{r}\right\}$ and $\mathscr{E}_{2} \ni F_{j}=\left\{y_{1}, \ldots, y_{s}\right\}$, where $\varphi^{\prime}$ is a surjective mapping $\varphi^{\prime}: F_{j} \rightarrow E_{k}$. This can only occur if $F_{j}=\{y\}$, hence $H_{2}$ would not be simple.
Analogously $E_{x j} \subseteq E_{i \varphi}$ can only be fulfilled if $H_{1}$ would not be simple.
Now suppose it holds $E \subseteq F$ where $E$ is non-Cartesian and $F$ is a Cartesian edge. Thus $\left|p_{i}(F)\right|=$ 1 for an $i \in\{1,2\}$ and therefore $\left|p_{i}(E)\right|=1$, but $p_{i}(E)$ must be an edge in $H_{i}$. Hence, one of the factors would not be simple.

## 2 Hypergraph Products

Because of associativity and commutativity, the strong product $H=\boxtimes_{i=1}^{n} H_{i}$ of arbitrary many factors $H_{i}$ is well defined. We can define this product in terms of projections as follows:

For $H=\boxtimes_{i=1}^{n} H_{i}, H_{i}=\left(V_{i}, \mathscr{E}_{i}\right)$ and $I=\{1, \ldots, n\}$ we have
(1) $V(H)=V_{1} \times V_{2} \times \ldots \times V_{n}$
(2) $E \in \mathscr{E}(H), E \subseteq V(H)$ if and only if there is a nonempty index set $J \subseteq I$, s.t.
(i) $p_{j}(E) \in E_{j}$ for all $j \in J$ and
(ii) $|E|=\left|p_{k}(E)\right|$ for a $k \in J$ and
(iii) $\left|p_{i}(E)\right|=1$ for all $i \in I \backslash J$.

The vertices of Cartesian edges differ in exactly one coordinate, i.e. $|J|=1$, the other edges, i.e. for which $|J|>1$ are non-Cartesian.

The set of Cartesian edges of a strong product $H=\boxtimes_{i=1}^{n} H_{i}$ generates a partial hypergraph $H^{\prime}$ of $H$ with $V\left(H^{\prime}\right)=V(H)$. This partial hypergraph is indeed the Cartesian product of the factors of $H, H^{\prime}=\square_{i=1}^{n} H_{i}$. We will call such a hypergraph $H^{\prime}$ the Cartesian skeleton of $H$. Therefore, it is clear, that the strong product is connected if and only if all of its factors are.
As for the Cartesian product each $H_{j}$-layer through an arbitrary vertex $w$ of a strong product $H=\boxtimes_{i=1}^{n} H_{i}$ is isomorphic to the factor $H_{j}$,

$$
\left\langle\left\{v \in V(H) \mid p_{k}(v)=w_{k} \text { for } k \neq j\right\}\right\rangle \cong H_{j} .
$$

## Summary

To conclude this section, we summarize the preceding results. For the strong product holds:

1. The restriction of this product on graphs is the strong graph product.
2. Associativity.
3. Commutativity.
4. Distributivity with respect to the disjoint union.
5. The product of two simple hypergraphs is simple.
6. The projections of a product hypergraph onto its factors are weak homomorphisms.

As an open problem, it remains to examine if this product has a unique prime factorization. But that would go beyond the scope of this thesis.

## 3 Unique Prime Factorization with Respect to the Cartesian Product

In this chapter we are concerned with the decomposition, more exactly the prime factor decomposition of a given hypergraph $H$ with respect to the Cartesian product.
Uniqueness of prime factorization of simple and connected hypergraphs was proved by W. Imrich in [23]. A factorization algorithm for a small class of hypergraphs, the conformal ${ }^{1}$ hypergraphs is given by A. Bretto et al. in [8]. They showed that the prime factorization of a Cartesian product of conformal hypergraphs can be reduced to prime factorization of a Cartesian product graph, namely its 2-section and then used the factorization algorithm for Cartesian graph products given in [30]. Here we give an alternative, more constructive proof for uniqueness of prime factor decomposition of simple connected hypergraphs and provide a product relation according to the unique prime factorization of a given simple connected hypergraph. The proof is modeled after the proof of unique prime factor decomposition of a Cartesian product graph by W. Imrich and J. Žerovnik in [32].

First, we have to introduce some further notations.
A Hypergraph $H$ is called prime with respect to a given product if it cannot be represented as the product of two nontrivial hypergraphs, i.e. for the Cartesian product, $H=H_{1} \square H_{2}$ implies $H_{1}=K_{1}$ or $H_{2}=K_{1}$. By a prime factorization of a hypergraph $H$ is meant a representation of $H$ as a Cartesian product hypergraph $H=\square_{i=1}^{n} H_{i}$ such that the $H_{i}$ are prime and $H_{i} \neq K_{1}$ for all $i \in\{1, \ldots, n\}$.

Let $H=A \square B$ be a Cartesian product such that $A$ and $B$ are both nontrivial Hypergraphs and let $A=A_{1} \square A_{2}$ be a nontrivial representation of $A$. Then we call the product representation $A_{1} \square A_{2} \square B$ a refinement of $A \square B$. Every sequence of refinements has to terminate as a product

[^2]
## 3 Unique Prime Factorization with Respect to the Cartesian Product

$H_{1} \square H_{2} \square \ldots \square H_{n}$ of prime hypergraphs, since every factor of a nontrivial hypergraph product has fewer vertices than the product itself. Thus we can state the following proposition.

Proposition 3.1. Every hypergraph $H$ has a prime factorization with respect to the Cartesian product. The number of prime factors is at most $\log _{2}|V(H)|$.

The latter statement comes from the fact that every nontrivial hypergraph has at least two vertices.

By Proposition 3.1, every hypergraph $H$ can be represented as a product $H=\square_{i=1}^{n} H_{i}$ of prime factors $H_{i}$. If $H$ itself is prime, we have $n=1$ and $H=H_{1}$. Since graphs are a special class of hypergraphs, prime factorization of non-connected hypergraphs with respect to the Cartesian product is not unique (see Theorem 1.1).

Remark 3.1. In the following we are concerned with simple connected hypergraphs.
Let $H=\square_{i=1}^{n} H_{i}$ be a Cartesian product of hypergraphs $H_{i}$. Recall that $E=\left\{v_{1}, \ldots, v_{r}\right\}$ is an edge in $H$ if and only if there is an $j \in\{1 \ldots, n\}$, such that $p_{j}(E)=\left\{p_{j}\left(v_{1}\right), \ldots, p_{j}\left(v_{r}\right)\right\} \in \mathscr{E}\left(H_{j}\right)$ and $p_{i}\left(v_{1}\right)=\ldots=p_{i}\left(v_{r}\right)$ for all $i \neq j$.

A product coloring on the edge set of $H=\square_{i=1}^{n} H_{i}$ is given by the mapping $c: \mathscr{E}(H) \rightarrow\{1, \ldots, n\}$ defined by $c(E)=j$ if the vertices of $E$ differ in the $j$-th coordinate.
An equivalence relation $\gamma$ on the edge set $\mathscr{E}(H)$ of a Cartesian product $H=\square_{i=1}^{n} H_{i}$ of (not neccessairily prime) hypergraphs $H_{i}$ is a product relation if $E$ and $F$ are in relation $\gamma$ if and only if there exists an $j \in\{1, \ldots, n\}$, such that

$$
\left|p_{j}(E)\right|>1 \quad \text { and } \quad\left|p_{j}(F)\right|>1
$$

for $E, F \in \mathscr{E}(H)$. It is clear, that $\left|p_{i}(E)\right|=\left|p_{i}(F)\right|=1$ holds for all $i \neq j$. If the $H_{i}$ are all prime, we denote this relation by $\sigma$. And in this case we have $E$ and $F$ are in relation $\sigma$ if and only if $c(E)=c(F)$. Thus, each equivalence class of $\sigma$ belongs to a prime factor of $H$. Moreover, let $\Sigma_{i}, i=1, \ldots, n$ be the equivalence classes of $\sigma$. Every connected component of a partial hypergraph generated by the edges of an equivalence class $\Sigma_{i}$ is isomorphic to $H_{i}$. Consider now the connected components of a partial hypergraph generated by the union of arbitrary equivalence classes of $\sigma, \bigcup_{j \in J} \Sigma_{j}, J \subseteq\{1, \ldots, n\}$. Each connected component of this partial hypergraph is then isomorphic to $H_{J}:=\square_{j \in J} H_{j}$.

Definition 3.1. Let $E_{1}, \ldots, E_{s}$ and $F_{1}, \ldots, F_{r}$ be edges of a hypergraph $H$. We say they form an $r \times s$-grid if
(i) $\left|E_{i} \cap F_{j}\right|=1$, and
(ii) $E_{i} \cap E_{i^{\prime}}=F_{j} \cap F_{j^{\prime}}=\emptyset$,
for all $i, i^{\prime} \in\{1, \ldots, s\}, j, j^{\prime} \in\{1, \ldots, r\}$, with $i \neq i^{\prime}, j \neq j^{\prime}$. If there is an edge $D \in \mathscr{E}(H)$, such that
(iii) $E_{k} \cap F_{l} \cap D \neq \emptyset$ and $E_{k^{\prime}} \cap F_{l^{\prime}} \cap D \neq \emptyset$
holds for $k, k^{\prime} \in\{1, \ldots, s\}$ and $l, l^{\prime} \in\{1, \ldots, r\}$ with $k \neq k^{\prime}$ and $l \neq l^{\prime}$, we call $D$ a diagonal of this $r \times s$-grid.

Figure 3.1: $r \times s$-Grid with diagonal $D$

Note, that for the edges $E_{1}, \ldots, E_{r}$ and $F_{1}, \ldots, F_{s}$ we have $\left|E_{i}\right|=s$ and $\left|F_{j}\right|=r$ for all $i \in$ $\{1, \ldots, r\}, j \in\{1, \ldots, s\}$.
Such a grid emerges, whenever two edges of two hypergraphs are multiplied with respect to the Cartesian product. This leads us to a relation $\delta$, defined as follows.

Definition 3.2. Let $H$ be a connected hypergraph. For $E, F \in \mathscr{E}(H)$ we say $E$ and $F$ are in relation $\delta$ if one of the following conditions holds:
(i) $E \cap F=\emptyset$ and $E$ and $F$ are opposite edges of a four-cycle
(ii) $E \cap F \neq \emptyset$ and there is no $(|E| \times|F|)$-grid without diagonals containing them.

Remark, that for $|E \cap F|>1$ there is no such $(|E| \times|F|)$-grid, hence $E \delta F$.
Obviously, the relation $\delta$ is reflexive and symmetric. The transitive closure $\delta^{*}$, i.e., the smallest transitive relation containing $\delta$, is then an equivalence relation. Condition (ii) implies, that any two incident edges $E, F$ with $(E, F) \notin \delta$ span an $(|E| \times|F|)$-grid without diagonals. Let this grid consist of the edges $E, E_{1}, \ldots, E_{s}$ and $F, F_{1}, \ldots, F_{r}$ with $E \delta E_{i}$ and $F \delta F_{j}$ for all $i \in\{1, \ldots, s\}$ and $j \in\{1, \ldots, r\}$, respectively. Suppose now there is another $(|E| \times|F|)$-grid consisting of edges $E, E_{1}^{\prime}, \ldots, E_{s}^{\prime}$ and $F, F_{1}^{\prime}, \ldots, F_{r}^{\prime}$.

Figure 3.2: Two edges $E$ and $F$, with $E \delta F$, which span more than one $|E| \times|F|$-grid

There must be a $k \in\{1, \ldots, s\}$ and an $l \in\{1, \ldots, r\}$ such that $E_{k}^{\prime} \notin\left\{E_{1}, \ldots, E_{s}\right\}$ and $F_{l}^{\prime} \notin$ $\left\{F_{1}, \ldots, F_{r}\right\}$, respectively, see Figure 3.2. Then there exists an $E_{i} \in\left\{E_{1}, \ldots, E_{s}\right\}$ as well as an $F_{j} \in\left\{F_{1}, \ldots, F_{r}\right\}$ with $\left|E_{k}^{\prime} \cap E_{i}\right| \neq 0$ and $\left|F_{l}^{\prime} \cap F_{j}\right| \neq 0$. Thus, there is a four cycle $E_{k}^{\prime} E_{i} F_{j} F_{l}^{\prime}$, where $E_{k}^{\prime}$ and $F_{j}$ as well as $E_{i}$ and $F_{l}^{\prime}$ are opposite edges. Hence $E_{k}^{\prime} \delta F_{j}$ and $E_{i} \delta F_{l}^{\prime}$, and therefore $(E, F) \in \delta^{*}$. Thus, if $E$ and $F$ belong to distinct $\delta^{*}$-equivalence classes, they span exactly one $(|E| \times|F|)$-grid. This leads us to the following definition:

Definition 3.3. Let $\gamma$ be an equivalence relation on the edge set $\mathscr{E}(H)$ of a hypergraph $H$. We say $\gamma$ has the grid property if any two adjacent edges $E$ and $F$ of $H$ of distinct $\gamma$-equivalence classes span exactly one diagonal free $|E| \times|F|$-grid.

As seen before, $\delta^{*}$ has the grid property. Let $\gamma$ be an arbitrary equivalence relation on the edge set of a hypergraph $H$ that contains $\delta^{*}$. For any two edges $E$ and $F$ with $(E, F) \notin \gamma$ holds
$(E, F) \notin \delta^{*}$ and therefore, they span exactly one $|E| \times|F|$-grid. Thus, any equivalence relation $\gamma$ with $\delta^{*} \subseteq \gamma$ satisfies the grid property.

Another relevant property satisfied by $\delta^{*}$ and any equivalence relation $\gamma$ with $\delta \subseteq \gamma$ is introduced in the next lemma.

Lemma 3.1. Let $\gamma$ be an equivalence relation on the edge set $\mathscr{E}(H)$ of a connected hypergraph $H$ with equivalence classes $\Gamma_{1}, \ldots, \Gamma_{k}$, which satisfies the grid property. Then every vertex of $V(H)$ is incident to edges of $\Gamma_{i}$ for all $i \in\{1, \ldots, k\}$.

Proof. Suppose there is an equivalence class $\Gamma_{i}$ of $\gamma$ such that there are vertices in $V(H)$ which are not contained in a $\Gamma_{i}$-edge. As $H$ is connected, there exists a pair of vertices $u, v \in V(H)$ and an edge $E \in \mathscr{E}(H)$ with $\{u, v\} \subseteq E$, such that $u$ belongs to a $\Gamma_{i}$-edge, say $F$ and there is no $\Gamma_{i}$-edge containing $v$. Then clearly, $E$ is not in $\Gamma_{i}$, it is in $\Gamma_{k}$ with $\Gamma_{k} \neq \Gamma_{i}$. But then $E$ and $F$ are two adjacent edges belonging to different equivalence classes of $\gamma$ and thus by the grid property there must be a $\Gamma_{i}$-edge containing $v$, which contradicts the assumption.

Lemma 3.2. Let $H=\square_{i=1}^{n} H_{i}$ be a Cartesian product of prime hypergraphs $H_{i}$ and let $E, F \in$ $\mathscr{E}(H)$. If $E$ and $F$ are in relation $\delta$, they are in relation $\sigma$.

Proof. Let the first condition in Definition 3.2 be satisfied, i.e., $E \cap F=\emptyset$ and there are edges $E^{\prime}, F^{\prime} \in \mathscr{E}(H)$ such that $E E^{\prime} F F^{\prime}$ build a four-cycle. Let $E=\left\{x_{1}, \ldots, x_{r}\right\}$ and $F=\left\{y_{1}, \ldots, y_{s}\right\}$. W.l.o.g. assume $x_{1} \in E \cap E^{\prime}, x_{r} \in E \cap F^{\prime}, y_{1} \in F \cap E^{\prime}, y_{s} \in F \cap F^{\prime}$. Let $c(E)=i, c(F)=j$, $c\left(E^{\prime}\right)=i^{\prime}, c\left(F^{\prime}\right)=j^{\prime}$.

Figure 3.3: 4-cycle $E E^{\prime} F F^{\prime}$

Then we have:

$$
\begin{array}{ll}
p_{k}\left(x_{1}\right)=p_{k}\left(x_{r}\right) & \text { for all } k \neq i \\
p_{k}\left(y_{1}\right)=p_{k}\left(y_{s}\right) & \text { for all } k \neq j \\
p_{k}\left(x_{1}\right)=p_{k}\left(y_{1}\right) & \text { for all } k \neq i^{\prime} \\
p_{k}\left(x_{r}\right)=p_{k}\left(y_{s}\right) & \text { for all } k \neq j^{\prime} . \tag{3.4}
\end{array}
$$

It follows from (3.1) and (3.3) that

$$
\begin{equation*}
p_{k}\left(x_{1}\right)=p_{k}\left(y_{s}\right) \quad \text { for all } k \neq i, j^{\prime} \tag{3.5}
\end{equation*}
$$

and from (3.2) and (3.4)

$$
\begin{equation*}
p_{k}\left(x_{1}\right)=p_{k}\left(y_{s}\right) \quad \text { for all } k \neq j, i^{\prime} . \tag{3.6}
\end{equation*}
$$

Therefore we have either $i=j$ and $i^{\prime}=j^{\prime}$ or $i=i^{\prime}$ and $j^{\prime}=j$. Assume $i \neq j$. Then the latter case must hold and we have $p_{k}\left(x_{r}\right)=p_{k}\left(x_{1}\right)=p_{k}\left(y_{i}\right)$ for all $k \neq i$, and since $x_{r} \neq y_{1}$ holds, $p_{i}\left(x_{r}\right) \neq p_{i}\left(y_{1}\right)=p_{i}\left(y_{s}\right)$ and $p_{j}\left(x_{r}\right) \neq p_{j}\left(y_{s}\right)$. So $x_{r}$ and $y_{s}$ differ in more than one coordinate, thus they cannot lie in the same edge $F^{\prime}$, which contradicts the assumption, so $i=j$ must hold, i.e. $c(E)=c(F)$ hence $E \sigma F$.

Now let $E$ and $F$ be adjacent edges of a hypergraph $H$, i.e., $|E \cap F|>0$ and suppose, there is no $|E| \times|F|$-grid without diagonals containing them.
First, consider the case $|E \cap F|>1$. There is an $i \in\{1, \ldots, n\}$ such that $\left|p_{i}(E)\right|>1$ and in particular, $\left|p_{i}\left(E^{\prime}\right)\right|>1$ holds for all $E^{\prime} \subseteq E$ with $\left|E^{\prime}\right|>1$. Since $(E \cap F) \subseteq E$ and $|E \cap F|>1$, it follows $\left|p_{i}(E \cap F)\right|>1$. But as $(E \cap F) \subseteq F$ we have $\left|p_{i}(F)\right|>1$ as well and therefore $E \sigma F$. Now let $|E \cap F|=1$ and suppose $E$ and $F$ are not in relation $\sigma$. Let $E \cap F=\{v\}$, say $E=$ $\left\{v, x_{1}, \ldots, x_{r}\right\}$ and $c(E)=i$ as well as $F=\left\{v, y_{1}, \ldots, y_{s}\right\}$ and $c(F)=j \neq i$. For all $x_{a} \in E$, $a \in\{1, \ldots, r\}$, there exists vertices $z_{a b} \in V(H)$, such that for all $b \in\{1, \ldots, s\}$ hold

$$
\begin{align*}
& p_{i}\left(z_{a b}\right)=p_{i}\left(x_{a}\right)  \tag{3.7}\\
& p_{k}\left(z_{a b}\right)=p_{k}\left(y_{b}\right) \quad \text { for all } k \neq i . \tag{3.8}
\end{align*}
$$

Then we have for the set $F_{a}=\left\{x_{a}, z_{a 1}, \ldots, z_{a s}\right\}$ :

$$
\begin{equation*}
p_{j}\left(F_{a}\right)=\left\{p_{j}\left(x_{a}\right), p_{j}\left(z_{a 1}\right), \ldots, p_{j}\left(z_{a s}\right)\right\}=\left\{p_{j}(v), p_{j}\left(y_{1}\right), \ldots, p_{j}\left(y_{s}\right)\right\}=p_{j}(F) \tag{3.9}
\end{equation*}
$$

as well as

$$
\begin{equation*}
p_{k}\left(z_{a 1}\right)=\ldots=p_{k}\left(z_{a s}\right)=p_{k}\left(y_{b}\right)=p_{k}(v)=p_{k}\left(x_{a}\right) \text { for all } k \neq i, j \tag{3.10}
\end{equation*}
$$

from (3.8) and the fact, that $\left\{v, y_{b}\right\} \subseteq F$ for all $b \in\{1, \ldots, s\}$ and $\left\{v, x_{a}\right\} \subseteq E$.
Now from (3.7) and (3.10) we gain

$$
\begin{equation*}
p_{k}\left(z_{a 1}\right)=\ldots=p_{k}\left(z_{a s}\right)=p_{k}\left(x_{a}\right) \quad \text { for all } k \neq i \tag{3.11}
\end{equation*}
$$

and therefore, from (3.9) and (3.11) it follows that $F_{a}$ is an edge in $H$ with $\left|F_{a}\right|=|F|$, for arbitrary $a \in\{1, \ldots, r\}$.
On the other hand, for the set $E_{b}=\left\{y_{b}, z_{1 b}, \ldots, z_{r b}\right\}$ holds

$$
\begin{equation*}
p_{i}\left(E_{b}\right)=\left\{p_{i}\left(y_{b}\right), p_{i}\left(z_{1 b}\right), \ldots, p_{i}\left(z_{r b}\right)\right\}=\left\{p_{i}(v), p_{i}\left(x_{1}\right), \ldots, p_{i}\left(x_{r}\right)\right\}=p_{i}(E) \tag{3.12}
\end{equation*}
$$

again from (3.7) and the fact that $\left\{v, y_{b}\right\} \subseteq F$ for all $b \in\{1, \ldots, s\}$. Together with (3.8) it follows that the $E_{b}$ for $b \in\{1, \ldots, s\}$ are edges in $H$.

Figure 3.4: Edges $E$ and $F$ (red edges) with $(E, F) \notin \sigma$ and the $|E| \times|F|$-grid they span

Furthermore, if we relabel $v$ as $z_{00}, E$ as $E_{0}, F$ as $F_{0}$ and the $x_{l}$ as $z_{l 0}$ for $l \in\{1, \ldots, r\}$, the $y_{l}$ as $z_{0 l}$ for $l \in\{1, \ldots, s\}$ respectively, we have $E_{b} \cap F_{a}=\left\{z_{a b}\right\}$ for all $a \in\{0, \ldots, r\}$ and $b \in\{0, \ldots, s\}$ respectively. Obviously, the intersection of more then two edges is empty. That means, whenever two adjacent edges $E$ and $F$ are not in relation $\sigma$, they span such an $|E| \times|F|$-grid with $|E| \times|F|$ vertices.
It remains to show that these grids have no diagonals. Therefore, we need to show that there is
no $D \in \mathscr{E}(H)$ such that $\left\{z_{a b}, z_{a^{\prime} b^{\prime}}\right\} \subseteq D$ for all $a, a^{\prime} \in\{0, \ldots, r\}, b, b^{\prime} \in\{0, \ldots, s\}$ with $a \neq a^{\prime}$ and $b \neq b^{\prime}$. For $z_{a b}, z_{a^{\prime} b^{\prime}}$ we have:

$$
\begin{align*}
& p_{i}\left(z_{a b}\right) \stackrel{(3.7)}{=} p_{i}\left(z_{a 0}\right) \neq p_{i}\left(z_{a^{\prime} 0}\right) \stackrel{(3.7)}{=} p_{i}\left(z_{a^{\prime} b^{\prime}}\right)  \tag{3.13}\\
& p_{j}\left(z_{a b}\right) \stackrel{(3.8)}{=} p_{j}\left(z_{0 b}\right) \neq p_{j}\left(z_{0 b^{\prime}}\right) \stackrel{(3.8)}{=} p_{j}\left(z_{a^{\prime} b^{\prime}}\right) \tag{3.14}
\end{align*}
$$

The inequalities follow from the fact, that $\left\{z_{a 0}, z_{a^{\prime} 0}\right\} \subseteq E_{0}$ and $\left\{z_{0 b}, z_{0 b^{\prime}}\right\} \subseteq F_{0}$.
That means that $z_{a b}$ and $z_{a^{\prime} b^{\prime}}$ differ in more than one coordinate, hence, they cannot be contained in the same edge, which completes the proof.

Lemma 3.2 implies that $\delta \subseteq \sigma$ and since $\sigma$ is an equivalence relation, even $\delta^{*} \subseteq \sigma$ holds, thus, $\sigma$ has the grid property.

In a hypergraph product $H=\square_{i=1}^{n} H_{i}$, the $H_{k}$-layers are convex partial hypergraphs, as we will see next. Even more, we can state:

Lemma 3.3. Let $H=\square_{i=1}^{n} H_{i}$ be a Cartesian product of connected hypergraphs $H_{i}$. Then each $H_{J}=\square_{j \in J} H_{j}$-layer is convex for any index set $J \subseteq\{1, \ldots, n\}$.

Proof. It suffices to show that whenever there is a path $P$ between two arbitrary vertices $u$ and $v$ of the same $H_{J}$-layer $H_{J}^{u}$, containing no edges of this layer, then there exists a path $Q$ which entirely lies in $H_{J}^{u}$ such that $|Q|<|P|$.
Suppose $P=\left(u=u_{0}, E_{1}, u_{1}, E_{2}, \ldots, u_{k-1}, E_{k}, u_{k}=v\right)$. Since $u$ and $v$ belong to the same $H_{j}$-layer, $p_{l}(u)=p_{l}(v)$ holds for all $l \in I_{n} \backslash J$. There must be an edge $E_{i}$ of $P$ such that $E_{i}$ is contained in some $H_{J}$ layer, by assumption different from $H_{J}^{u}$. Otherwise we would have $p_{l}(u)=p_{l}(v)$ for all $l \in J$, hence $p_{l}(u)=p_{l}(v)$ for all $l \in I_{n}$, i.e. $u=v$.
Let $\left\{E_{j_{1}}, \ldots, E_{j_{r}}\right\}$ be a subset of edges of $P$, with $j_{1}, j_{2}, \ldots, j_{r} \in\{1, \ldots, k\}, j_{1}<j_{2}<\ldots<j_{r}$, that are in some $H_{J}$-layer different from $H_{J}^{u}$, and no edge is the copy of another. To be more precise, for each $j_{i}$ there is a $k_{i} \in J$ with

$$
\begin{equation*}
p_{k_{i}} E_{j_{i}} \in \mathscr{E}\left(H_{k_{i}}\right) \quad \text { and } \quad p_{k_{a}} E_{j_{a}} \neq p_{k_{b}} E_{j_{b}} \quad \text { for } a \neq b \tag{3.15}
\end{equation*}
$$

and $j_{r}$ is maximal. Notice, that $a \neq b$ does not imply $k_{a} \neq k_{b}$.
By assumption $E_{1}$ is not contained in any $H_{J}$-layer, thus $r<k$. Without loss of generality, we can assume that the $E_{j_{i}}$ are not incident. In the following we will denote the vertices $u_{j_{i}}$ by $j_{i}$. If

3 Unique Prime Factorization with Respect to the Cartesian Product
we set $j_{0}:=u_{0}$, we have

$$
\begin{equation*}
p_{l}\left(j_{i-1}\right)=p_{l}\left(j_{i}-1\right) \quad \text { for all } l \in J \text { and all } i \in\{1, \ldots, r\} \tag{3.16}
\end{equation*}
$$

and since $j_{i}-1, j_{i} \in E_{j_{i}}$,

$$
\begin{equation*}
p_{l}\left(j_{i}\right)=p_{l}\left(j_{i}-1\right) \tag{3.17}
\end{equation*}
$$

holds for all $l \neq k_{i}, k_{i} \in J$.

Figure 3.5: Idea of the proof: Path $P$ (black) and Path $Q$ (red) which we got by shifting the edges $E_{j_{i}}$ in the $H_{J}^{u}$-layer

Furthermore, for each $j_{i}, i \in\{1, \ldots, r\}$, there exists a $v_{i} \in V(H)$, such that

$$
\begin{array}{ll}
p_{l}\left(v_{i}\right)=p_{l}(u) & \text { for all } l \in I_{n} \backslash J \\
p_{l}\left(v_{i}\right)=p_{l}\left(j_{i}\right) & \text { for all } l \in J \tag{3.19}
\end{array}
$$

In particular, Equation (3.18) implies $v_{i} \in V\left(H_{J}^{u}\right)$ for all $i \in\{1, \ldots, r\}$. It follows

$$
\begin{equation*}
p_{l}\left(v_{i-1}\right) \stackrel{(3.19)}{=} p_{l}\left(j_{i-1}\right) \stackrel{(3.16),(3.17)}{=} p_{l}\left(j_{i}\right) \stackrel{(3.19)}{=} p_{l}\left(v_{i}\right) \quad \text { for all } l \in J \backslash\left\{k_{i}\right\} \tag{3.20}
\end{equation*}
$$

and by Equation (3.18) we have

$$
\begin{equation*}
p_{l}\left(v_{i-1}\right)=p_{l}\left(v_{i}\right) \quad \text { for all } l \in I_{n} \backslash J \tag{3.21}
\end{equation*}
$$

## 3 Unique Prime Factorization with Respect to the Cartesian Product

hence by Equations (3.20) and (3.21)

$$
\begin{equation*}
p_{l}\left(v_{i-1}\right)=p_{l}\left(v_{i}\right) \quad \text { for all } l \neq k_{i} \tag{3.22}
\end{equation*}
$$

In other words, each two vertices $v_{i-1}, v_{i}$ lie in the same $H_{k_{i}}$ layer for some $k_{i} \in J$.
Next we show that there are edges $F_{i} \in \mathscr{E}\left(H_{J}^{u}\right)$ containing both $v_{i-1}$ and $v_{i}$. From Equations (3.16) and (3.19) it follows

$$
\begin{align*}
& p_{k_{i}}\left(v_{i-1}\right) \stackrel{(3.19)}{=} p_{k_{i}}\left(j_{i-1}\right) \stackrel{(3.16)}{=} p_{k_{i}}\left(j_{i}-1\right)  \tag{3.23}\\
& \quad p_{k_{i}}\left(v_{i}\right) \stackrel{(3.19)}{=} p_{k_{i}}\left(j_{i}\right) \tag{3.24}
\end{align*}
$$

Thus we have by Equations (3.23), (3.24) and (3.15)

$$
\begin{equation*}
p_{k_{i}}\left(v_{i-1}\right), p_{k_{i}}\left(v_{i}\right) \in p_{k_{i}}\left(E_{j_{i}}\right) \tag{3.25}
\end{equation*}
$$

Hence by Equations (3.18), (3.22) and (3.25), for each $i \in\{1, \ldots, r\}$ there exists an edge $F_{i}$ in $H_{J}^{u}$, such that $v_{i-1}, v_{i} \in F_{i}$.
Consider now $v_{r}$. Since there is no more edge $E_{j}, j>j_{r}$, of $P$ that is contained in any $H_{J}$-layer, $j_{r}$ and $v$ belong to the same $\widehat{H_{J}}:=\square_{i \in I_{n} \backslash J} H_{i}$-layer, and therefore we have

$$
\begin{equation*}
p_{l}\left(v_{r}\right) \stackrel{(3.19)}{=} p_{l}\left(j_{r}\right)=p_{l}(v) \quad \text { for all } l \in J \tag{3.26}
\end{equation*}
$$

and from the definition of $v_{r}$ and the fact that $u$ and $v$ are in the same $H_{J}$-layer, it follows

$$
\begin{equation*}
p_{l}\left(v_{r}\right) \stackrel{(3.18)}{=} p_{l}(v) \quad \text { for all } l \in I_{n} \backslash J . \tag{3.27}
\end{equation*}
$$

Therefore, we can conclude $v_{r}=v$, and we found a path $Q=\left(u=v_{0}, F_{1}, v_{1}, \ldots, v_{r-1}, F_{r}, v_{r}=v\right)$ from $u$ to $v$, whose edges entirely lie in $H_{J}^{u}$ and for which holds

$$
|Q|=r<k=|P|,
$$

which completes the proof.

This gives rise to the next definition.
Definition 3.4. An equivalence relation $\gamma$ on the edge set $\mathscr{E}(H)$ of a hypergraph $H$ with equivalence classes $\Gamma_{i}, i \in I$, is called convex iffor any $J \subseteq I$ every connected component of the partial hypergraph generated by $\bigcup_{i \in J} \Gamma_{i}$ is convex.

By Lemma 3.3, the product relation $\sigma$ is a convex relation. Moreover, any product relation must be convex and has to satisfy the grid property. On the other hand, we have the following statement

Theorem 3.1. Let $\gamma$ be a convex equivalence relation on the edge set $\mathscr{E}(H)$ of a connected Hypergraph $H$ which satisfies the grid property. Then $\gamma$ induces a factorization of $H$ with respect to the Cartesian product.

To prove this theorem, we first have to show the validity of the next two lemmas.
Lemma 3.4. Let $\gamma$ be an equivalence relation on the edge set $\mathscr{E}(H)$ of a connected hypergraph $H$ which satisfies the grid property. Let $\Gamma$ be an equivalence class of $\gamma$. If all connected components of the partial hypergraph of $H$ generated by $\Gamma$ are convex, they are isomorphic.

Proof. Let $H_{\Gamma}$ be the partial hypergraph generated by $\Gamma$ with connected components $C_{1}, \ldots, C_{r}$ and let $\widehat{\Gamma}$ denote the union of all equivalence classes of $\gamma$, distinct from $\Gamma$, i.e., $\widehat{\Gamma}=\bigcup_{\Gamma^{\prime} \neq \Gamma} \Gamma^{\prime}$. It suffices to show, that any two components $C_{1}, C_{2}$ which are connected by a $\widehat{\Gamma}$-edge are isomorphic. We define a mapping $\varphi: V\left(C_{1}\right) \rightarrow V\left(C_{2}\right)$, through $x \mapsto \varphi x$, whenever $x$ and $\varphi x$ are connected by a $\widehat{\Gamma}$-edge. From the grid property and Lemma 3.1, it follows that for all $x \in V\left(C_{1}\right)$ there exists a $\varphi x \in V\left(C_{2}\right)$. The grid property ensures that adjacent vertices in $C_{1}$ have different images in $C_{2}$ and edges in $C_{1}$ map onto edges in $C_{2}$. By convexity we have, that non adjacent vertices in $C_{1}$ have different images in $C_{2}$ as well, i.e. the mapping $\varphi$ is injective. On the other hand we can extend $\varphi^{-1}$ to a mapping $\psi: V\left(C_{2}\right) \rightarrow V\left(C_{1}\right)$. Analogously, it follows that for all $y \in V\left(C_{2}\right)$ there is a $\psi y$ in $V\left(C_{1}\right)$, hence $\varphi^{-1}=\psi$, i.e. $\varphi$ is bijective, and every edge in $C_{2}$ maps onto an edge in $C_{1}$, thus $\varphi$ is an isomorphism between $C_{1}$ and $C_{2}$.

Sometimes the transitive closure of $\delta$ is already convex. If this is the case, then each path between two vertices of the same connected component of an equivalence class of $\delta^{*}$ must contain at least one edge of this equivalence class (see Lemma 3.3).

Figure 3.6 shows a hypergraph where $\delta^{*}$ is not convex and thus, the mapping $\varphi$ defined in the proof of Lemma 3.4 is no isomorphism. The connected component $C_{1}$ of the black equivalence class is mapped via the red edges onto the connected component $C_{2}$. Although $\varphi$ preserves adjacency and non-adjacency, the mapping is not isomorphic, since it is not injective.

Figure 3.6: Hypergraph and its equivalence classes (red and black, respectively) of $\delta^{*}$, and the connected components $C_{1}$ and $C_{2}$ of the hypergraph generated by the black equivalence class. We have $d_{H}(1,9)=2$, while $d_{C_{1}}(1,9)=3$, hence $C_{1}$ is not convex.

Lemma 3.5. Let $\gamma$ be an equivalence relation on the edge set $\mathscr{E}(H)$ of a connected hypergraph $H$ satisfying the grid property with only two equivalence classes $\Gamma$ and $\widehat{\Gamma}$. Let $H_{\Gamma}$ and $H_{\widehat{\Gamma}}$ be the subgraphs generated by $\Gamma$ and $\widehat{\Gamma}$, with connected components $C_{1}, \ldots, C_{r}$ and $\widehat{C}_{1}, \ldots, \widehat{C}_{s}$, respectively. Then

$$
V\left(C_{i}\right) \cap V\left(\widehat{C}_{j}\right) \neq \emptyset \text { for all } i \in\{1, \ldots, r\}, j \in\{1, \ldots, s\} .
$$

In particular,

$$
\left|V\left(C_{i}\right) \cap V\left(\widehat{C}_{j}\right)\right|=1
$$

holds if $C_{i}$ and $\widehat{C}_{j}$ are convex.
Proof. Suppose there are components $C_{i}, \widehat{C}_{j}$ with $V\left(C_{i}\right) \cap V\left(\widehat{C}_{j}\right)=\emptyset$, such that they have minimal distance. Let $P=\left(v_{0}, E_{1}, v_{1}, E_{2}, \ldots, E_{k}, v_{k}\right)$ be a shortest path from $C_{i}$ to $\widehat{C}_{j}$, such that $v_{0} \in V\left(C_{i}\right)$ and $v_{k} \in V\left(\widehat{C}_{j}\right)$. Obviously, the first edge $E_{1}$ must lie in $\widehat{\Gamma}$ and the vertex $v_{1}$ is not in $C_{i}$, otherwise $E_{1}$ would be in $\Gamma$ which contradicts the minimality of $P$. Lemma 3.1 implies, that $v_{1}$ must be contained in a $\Gamma$-component, say $C_{k}$. Since the distance from $C_{k}$ to $\widehat{C}_{j}$ is smaller than $|P|$, we have $V\left(C_{k}\right) \cap V\left(\widehat{C}_{j}\right) \neq \emptyset$. Let $w$ be a vertex in $V\left(C_{k}\right) \cap V\left(\widehat{C}_{j}\right)$ and let $P^{\prime}$ be a path from $v_{1}$ to $w$ in $C_{k}$. By repeated application of the grid property we gain a vertex $u$ in $V\left(C_{i}\right)$ connected to $w$ by a $\widehat{\Gamma}$-edge. But then $u$ must be in $V\left(\widehat{C}_{j}\right)$ and thus $\left|V\left(C_{i}\right) \cap V\left(\widehat{C}_{j}\right)\right| \geq 1$.
Now assume $\left|V\left(C_{i}\right) \cap V\left(\widehat{C}_{j}\right)\right| \geq 2$. Let $u, w \in V\left(C_{i}\right) \cap V\left(\widehat{C}_{j}\right)$. By connectivity we have a path $Q$ from $u$ to $w$ in $C_{i}$ and a path $Q^{\prime}$ from $u$ to $w$ in $\widehat{C}_{j}$ as well. Therefore either $|Q|>\left|Q^{\prime}\right|$ or

## 3 Unique Prime Factorization with Respect to the Cartesian Product

$\left|Q^{\prime}\right|>|Q|$ or $|Q|=\left|Q^{\prime}\right|$ holds. Hence either $C_{i}$ or $\widehat{C}_{j}$ or both are not convex. And therefore the second proposition holds.

We are now able to prove Theorem 3.1:
Proof of Theorem 3.1. First assume $\gamma$ has only two equivalence classes $\Gamma$ and $\widehat{\Gamma}$ with connected components $C_{1}, \ldots, C_{r}$ and $\widehat{C}_{1}, \ldots, \widehat{C}_{s}$ respectively, of the generated partial hypergraphs. By Lemma 3.5 we can assign uniquely determined coordinates $(i, j)$ to each vertex of $H$, whenever $\{v\}=V\left(C_{i}\right) \cap V\left(\widehat{C}_{j}\right), i \in\{1, \ldots, r\}, j \in\{1, \ldots, s\}$. On the other hand for all such coordinates there exists a uniquely determined vertex in $V(H)$, since $\left|V\left(C_{i}\right) \cap V\left(\widehat{C}_{j}\right)\right|=1$.
In the following we will identify each vertex of $H$ with its coordinates. Obviously we have $V\left(C_{i}\right)=\{(i, 1), \ldots,(i, s)\}$ for all $i \in\{1, \ldots, r\}$ and $V\left(\widehat{C}_{j}\right)=\{(1, j), \ldots,(r, j)\}$ for all $j \in\{1, \ldots, s\}$. Recall that Lemma 3.4 implies that the $C_{i}$ are isomorphic for all $i \in\{1, \ldots, r\}$. In particular $C_{1} \cong C_{i}$ holds for all $i \in\{1, \ldots, r\}$. The isomorphism is given by the mapping

$$
(1, j) \mapsto(i, j) \quad \text { for all } \quad j \in\{1, \ldots, s\} .
$$

If $C_{1}$ and $C_{i}$ are connected by an edge, it is an isomorphism as in the proof of Lemma 3.4. If they are connected by a path, it is an isomorphism by induction on the length of the path. Analogously we have $\widehat{C}_{1} \cong \widehat{C}_{j}$ for all $j \in\{1, \ldots, s\}$ given by the isomorphism

$$
(i, 1) \mapsto(i, j) \quad \text { for all } \quad i \in\{1, \ldots, r\} .
$$

A set of vertices $\left\{\left(i_{1}, j_{1}\right), \ldots,\left(i_{q}, j_{q}\right)\right\}, 1 \leq i_{1}, \ldots, i_{q} \leq r, 1 \leq j_{1}, \ldots, j_{q} \leq s$, is an edge in $H$ if and only if either
(i) it is in the same $C_{i}$, hence $i_{1}=\ldots=i_{q}=i$ and $\left\{\left(1, j_{1}\right), \ldots,\left(1, j_{q}\right)\right\}$ is an edge in $C_{1}$, or
(ii) it is in the same $\widehat{C}_{j}$, hence $j_{1}=\ldots=j_{q}=j$ and $\left\{\left(i_{1}, 1\right), \ldots,\left(i_{q}, 1\right)\right\}$ is an edge in $\widehat{C}_{1}$.

That is, $H$ is isomorphic to $C_{1} \square \widehat{C}_{1}$.
Now define hypergraphs $H_{1}$ and $H_{2}$ by setting $V\left(H_{1}\right)=\left\{i:(i, 1) \in V\left(C_{1}\right)\right\}$ and $V\left(H_{2}\right)=\{j$ : $\left.(1, j) \in V\left(\widehat{C}_{1}\right)\right\} . H_{1}$ and $H_{2}$ are isomorphic to $C_{1}$ and $\widehat{C}_{1}$ by the isomorphic mappings $i \mapsto(i, 1)$ and $j \mapsto(1, j)$ respectively, thus $H=H_{1} \square H_{2}$.
Assume now $\gamma$ has arbitrarily many equivalence classes $\Gamma_{i}, i=1, \ldots, n$. Let $\gamma_{i}$ be the equivalence relation with the two equivalence classes $\Gamma_{i}$ and $\widehat{\Gamma}_{i}=\bigcup_{k=1, k \neq i}^{n} \Gamma_{k}$ for arbitrary $i \in\{1, \ldots, n\}$. As already shown, we get a factorization of $H$ into two factors $H_{i} \square \widehat{H}_{i}$ where $H_{i}$ and $\widehat{H}_{i}$ belong to $\Gamma_{i}$

## 3 Unique Prime Factorization with Respect to the Cartesian Product

and $\widehat{\Gamma}_{i}$, respectively. We will call the projection, to be more precise, the image of the projection of a vertex $v$ in $H_{i} \square \widehat{H}_{i}$ into the factor $H_{i}$ the $i$-th coordinate of $v$, denoted by $v^{i}$.
Now it is clear, that we can assign coordinates to each vertex. If two vertices $u, v$ have the same $i$-th coordinate, then, by convexity, there is no $\Gamma_{i}$-edge on any shortest path between them. Thus, if $u$ and $v$ have the same coordinates, there is no nontrivial shortest path between them, hence $u=v$. Therefore the assignment of coordinates to vertices of a connected hypergraph $H$ is bijective.
A subset $\left\{v_{1}, \ldots, v_{r}\right\}$ of $V(H)$ is an edge of $H$ if and only if the $v_{k}$ differ in the same coordinate, say the $i$-th, for all $k \in\{1, \ldots, r\}$ and $\left\{v_{1}^{i}, \ldots, \nu_{r}^{i}\right\}$ is an edge in $H_{i}$.
Thus we have $H=\square_{i=1}^{n} H_{i}$.

The equivalence relation whose only equivalence class is the whole edge set of a hypergraph $H$ is trivially convex and satisfies the grid property and is therefore a product relation. And this relation always exists. By Theorem 3.1 we can conclude that any convex relation on the edge set of a connected hypergraph that satisfies the grid property is a product relation and induces a factorization of this hypergraph. The smallest convex relation satisfying the grid-property, if such a relation exists at all, must therefore induce a prime factorization with respect to the Cartesian product.

The following lemma is true for graphs, see [32], but it can immediately be transfered to hypergraphs.

Lemma 3.6. Let $\gamma_{j}, j \in J$ be an arbitrary set of convex relations on the Edge set $\mathscr{E}(H)$ of a hypergraph $H$ containing $\delta$. Then $\gamma=\bigcap_{j \in J} \gamma_{j}$ is convex.

It is clear that for arbitrary equivalence relations on the edge set of a hypergraph, which satisfy the grid-property, their intersection also has the grid-property. Therefore Lemma 3.6 implies that there is exactly one finest convex equivalence relation on the edge set $\mathscr{E}(H)$ of a hypergraph $H$ satisfying the grid property, namely the intersection of all convex relations on $\mathscr{E}(H)$ containing $\delta$, that is its convex hull, $\mathrm{C}(\delta)$. Conversely, any product relation must be convex and contains $\delta$. Thus we have proved the following theorems.

Theorem 3.2. Every connected hypergraph H has a unique prime factor decomposition with respect to the Cartesian product.

Theorem 3.3. The relation corresponding to the unique prime factorization of a connected hypergraph $H$ is the convex hull of $\delta$, i.e. $\sigma=\mathcal{C}(\delta)$.

## 4 Conclusion

### 4.1 Additional Notes

Only finite hypergraphs and products of finitely many factors are treated in this thesis. It is possible to extend the definitions of the Cartesian, the direct and the strong product to infinitely many graphs.

In particular, we have for the Cartesian product:
Let $\left\{H_{i} \mid i \in I\right\}$ be a set of (finite or infinite) hypergraphs. Then their Cartesian product, $\square_{i \in I} H_{i}$, is the following hypergraph:
(1) $V\left(\square_{i \in I} H_{i}\right)=\times_{i \in I} V\left(H_{i}\right)$,
(2) for $E \subseteq \times_{i \in I} V\left(H_{i}\right)$ we have $E \in \mathscr{E}\left(\square_{i \in I} H_{i}\right)$ if and only if there is an $i \in I$, s.t.
(i) $p_{i}(E) \in \mathscr{E}\left(H_{i}\right)$ and
(ii) $\left|p_{j}(E)\right|=1$ for all $j \in I \backslash\{i\}$.

While a Cartesian product hypergraph of finitely many connected hypergraphs is connected, whether they are finite or not, this does not hold for the product of infinitely many hypergraphs. Since in a product of infinitely many factors there are vertices that differ in infinitely many coordinates and thus, cannot be connected by a path of finite length, as vertices of the same edge differ in only one coordinate. An infinite connected hypergraph can have infinitely many prime factors with respect to the Cartesian product. In this case it cannot be the Cartesian product of these factors, since the product is not connected, but a connected component of this product. Therefore it might be useful to define a so called weak Cartesian product.
Let $\left\{H_{i} \mid i \in I\right\}$ be a family of hypergraphs and let $a_{i} \in V\left(H_{i}\right)$ for $i \in I$. The weak Cartesian product $H=\square_{i \in I}\left(H_{i}, a_{i}\right)$ of the rooted hypergraphs $\left(H_{i}, a_{i}\right)$ is defined by

$$
\begin{aligned}
& V(H)=\left\{v \in \underset{i \in I}{\left.\times V\left(H_{i}\right) \mid p_{i}(v) \neq a_{i} \text { for at most finitely many } i \in I\right\}}\right. \\
& \mathscr{E}(H)=\left\{E \subseteq V(H) \mid p_{j}(E) \in \mathscr{E}\left(H_{j}\right) \text { for exactly one } j \in I, \text { and }\left|p_{i}(E)\right|=1 \text { for } i \neq j\right\} .
\end{aligned}
$$

## 4 Conclusion

We will also write $\square_{i \in I}^{a} H_{i}$ instead of $\square_{i \in I}\left(H_{i}, a_{i}\right)$, with $a \in V(H)$, such that $p_{i}(a)=a_{i}$ for all $i \in I$. The weak Cartesian product of connected hypergraphs is connected. In this case, it is the connected component of the Cartesian product of the hypergraphs $H_{i}$ which contains $a$. One observes that the weak Cartesian product does not depend on the $a_{i}$ and is the Cartesian product if $I$ is finite. It is shown in [24] by W. Imrich, that every connected graph has a unique prime factor decomposition with respect to the weak Cartesian product. In this contribution, the author also extends the results to set systems, i.e. hypergraphs.
The proof of uniqueness of the prime factorization with respect to the Cartesian product of hypergraphs in Chapter 3 is modeled after the proof of uniqueness of prime factorization with respect to the weak Cartesian product of graphs in [32]. Therefore, with small modifications of the notations in Chapter 3, we can extend Theorem 3.2 to the following statement:

Theorem 4.1. Every connected hypergraph has a unique representation as a weak Cartesian product.

### 4.2 Summary

In this diploma thesis we studied hypergraph products as a generalization of the commutative standard graph products. The Cartesian product, which we were concerned with in Section 2.1 was already defined by W. Imrich in 1967 [23].

In Section 2.2 and Section 2.3 we defined some new hypergraph products. That are the direct product $\check{\times}$, the direct product $\times$, the direct product $\tilde{\times}$, and the strong product $\boxtimes$. Table 4.1 shows what kind of hypergraph products, treated in this thesis, fulfills which of the following properties:

1. $V\left(H_{1} \star H_{2}\right)=V\left(H_{1}\right) \times V\left(H_{2}\right)$.
2. If $H_{1}$ and $H_{2}$ are simple then $H_{1} \star H_{2}$ is simple.
3. The adjacency properties of a product depends on those of its factors.
4. Associativity.
5. Commutativity.
6. Distributivity with respect to the disjoint union.
7. The projections $p_{i}: V\left(H_{1} \star H_{2}\right) \rightarrow V\left(H_{i}\right)$ for $i \in\{1,2\}$ are (at least weak) homomorphisms.

## 4 Conclusion

8. The restriction of the product $\star$ on graphs is the corresponding graph product.
9. The product $H_{1} \star H_{2}$ is connected whenever the factors $H_{1}$ and $H_{2}$ are connected.
10. Unique prime factorization in the class of simple connected hypergraphs (or more special hypergraph classes).

| Properties | Cartesian $\square$ | Direct $\check{\times}$ | Direct $\times$ | Direct $\tilde{\times}$ | Strong $\boxtimes$ |
| :--- | :---: | :---: | :---: | :---: | :---: |

Table 4.1: Properties of the hypergraph products
*: Prime factorization w.r.t. the direct product $\check{x}$ is not unique in the class of conformal hypergraphs (cf. Example 2.2).

According to graph products, we will call hypergraph products which satisfy the first three conditions simple hypergraph products.

Uniqueness of the prime factor decomposition of simple connected hypergraphs was first proved by W. Imrich in [23]. We gave an alternative proof and showed, that the product relation corresponding to the unique prime factorization is the convex hull of a starting relation $\delta$ on the edge set of a given hypergraph.

### 4.3 Outlook

To conclude this thesis some open problems will be listed in the following. This listing makes no claim to be complete.

## 4 Conclusion

Other Products As seen in Section 2.2 of this thesis, there are not fewer than three hypergraph products that coincide with the direct graph product at least in the class of graphs without loops. Also three different definitions of hypergraph products that coincide with the strong graph product in this graph class may arise, here we considered only one product. Besides, it is shown for graphs, that there exists 256 simple graph products. Four of them are associative and the projections of a product into at least one of its factors are weak homomorphisms [26]. Obviously one question is if there are more hypergraph products than mentioned here, generalizing the common graph products. Moreover, how many simple hypergraph products do exist at all?

Prime Factorization A product relation $\sigma$, that belongs to the unique prime factorization of a simple connected hypergraph with respect to the Cartesian product, is provided in this thesis. This could be the basis for developing decomposition algorithms. One might ask in this context, which complexity of time and space is needed to compute the prime factors of a given hypergraph.

Also prime factor decomposition with respect to the strong and direct product of hypergraphs should be considered. At first, it remains to examine if the prime factorization with respect to the direct product and the strong product, respectively, is unique in special classes of hypergraphs. In graph theory, direct and strong graph products can be factorized by identifying their Cartesian skeleton and decompose it into its prime factors, see [16, 22]. The question is if this works for hypergraphs as well, and if it is easy to identify the Cartesian skeleton in this case.

Partial Hypergraphs of Product Hypergraphs In graph theory also subgraphs of product graphs are studied. The focus lies on isometric embeddings and retracts of the Cartesian and strong products, see for example [18, 27, 39]. It is shown, that every graph can be embedded isometrically into a strong product of paths [29].

Also graphs which can be represented as nontrivial subgraphs (i.e., each projection of this subgraphs into the factors contains at least two vertices) of Cartesian product graphs are of interest. Those graphs, for which such a representation is not possible are called $S$-prime and an infinite family of such graphs is classified for example in [33].

It is to examine if similar results also hold for hypergraphs.

Directed Hypergraphs In this thesis, only undirected hypergraphs are treated. But also directed hypergraphs are applied in various fields, see [2] for a survey. There are several ways to generalize the concept of directed graphs to directed hypergraphs. We give here a definition that

## 4 Conclusion

can be found in [17], since most of the others can be seen as a special case of this definition.
A directed hyperedge or hyperarc is an ordered pair, $E=(X, Y)$, of (possibly empty) disjoint subsets of vertices; $X$ is the tail of E while $Y$ is its head. The tail and the head of hyperarc E will be denoted by $T(E)$ and $H(E)$, respectively. A directed hypergraph is a hypergraph with directed hyperedges.

One might ask if the results of this thesis can be easily extended to directed hypergraphs.

## Erklärung

Ich versichere, dass ich die vorliegende Arbeit selbstständig und nur unter Verwendung der angegebenen Quellen und Hilfsmittel angefertigt habe.

Lydia Gringmann

[^0]:    ${ }^{1}$ A graph product is a simple product, if the product of simple graphs is a simple graph, the vertex set of a product is the Cartesian product of the vertex sets of its factors and adjacency in the product depends on the adjacency properties of the projections of pairs of vertices into the factors.

[^1]:    ${ }^{1}$ A graph $G$ is called bipartite if its vertex set can be represented as the union of two disjoint sets $V_{1}$ and $V_{2}$, such that no edge of $G$ joins vertices within $V_{1}$ and $V_{2}$, respectively.

[^2]:    ${ }^{1}$ A hypergraph $H$ is conformal if, for every $E \subseteq V(H), E$ is a maximal clique of $[H]_{2}$ iff $E$ is a hyperedge of $H$. The 2-section $[H]_{2}$ of a hypergraph $H$ is the graph whose vertices are the vertices of $H$, and where two vertices are adjacent iff they belong to a same hyperedge.
